Abstract. A new treatment of data refinement in typed lambda calculus is proposed, phrased in terms of prelogical relations \cite{HS99} rather than logical relations, and incorporating a constructive element. Constructive data refinement is shown to have desirable properties, and a substantial example of refinement is presented.

1 Introduction

One of the activities involved in developing programs from specifications is the transformation of “abstract programs” involving types of data that are not normally available as primitive in programming languages (graphs, sets, etc.) into “concrete programs” in which a representation of these in terms of simpler types of data is provided. Apart from the change to data representation, such data refinement should have no effect on the results computed by the program: the concrete program should be equivalent to the abstract program in the sense that all computational observations should return the same results in both cases.

The standard treatment of data refinement in the context of typed lambda calculus, originating with Reynolds in \cite{Rey81,Rey83} but described most clearly in \cite{Ten94}, cf. Sect. 8.5 of \cite{Mit96}, uses logical relations to prove the correctness of refinements. This work has its roots in \cite{Hoa72}, which proposes that the correctness of the concrete program be verified using an invariant on the domain of concrete values together with a function mapping concrete values (that satisfy the invariant) to abstract values. In algebraic terms, what is required is a homomorphism from a subalgebra of the concrete algebra to the abstract algebra. A strictly more general method is to take a homomorphic relation (a so-called correspondence \cite{Sch90}, cf. \cite{Mil71}) in place of a homomorphism from a subalgebra. Logical relations extend these ideas to deal with higher-order functions.

Proof method (\cite{Ten94}). Let \( A \) and \( B \) be \( \Sigma \)-Henkin models and let \( OBS \), the observable types, be a subset of \( \text{Types}(\Sigma) \). To show that \( B \) is a refinement of \( A \), find a logical relation \( R \) over \( A \) and \( B \) such that \( R^\sigma \) is the identity relation for each \( \sigma \in OBS \). We then say that \( B \) is a logical refinement of \( A \) and write \( A \leadsto B \), or \( A \overset{R}{\leadsto} B \) when we want to make \( R \) explicit.
It is well-known that the composition of two logical relations is not in general a logical relation. It follows that, given logical refinements $A \rightarrow^R B$ and $B \rightarrow^S C$, the composition $S \circ R$ cannot in general be used as a witness for the composed refinement $A \rightarrow C$. (In fact, the problem is more serious than it appears at first: sometimes there is no witness for $A \rightarrow C$ at all, see Sect. 3.) This is at odds with the stepwise nature of refinement, and the transitivity of the underlying concept of refinement expressed in terms of observational equivalence. It is one source of examples demonstrating the incompleteness of the above proof method; there are other examples that do not involve composition of refinement steps, see e.g. Sect. 5. The proof method is complete in the absence of higher-order term constants [Mit96].

In [HS99], a weakening of the notion of logical relations called pre-logical relations was studied; cf. [PPST00]. Pre-logical relations are closed under composition; in fact, they are the minimal weakening of logical relations with this property. They completely characterize observational equivalence of Henkin models, without restriction to first-order signatures. Replacing logical relations with pre-logical relations in the above gives a notion of pre-logical refinement which is in pleasing harmony with stepwise refinement. Indeed, it is equivalent to the underlying concept of refinement, i.e. sound and complete as a proof method.

This is an improvement but pre-logical refinement still does not entirely accord with our intuition concerning data refinement and stepwise development of programs. For one thing, like logical refinement it is a symmetric relation. We will consider a more elaborate notion of data refinement, called constructive pre-logical refinement (Sect. 4). This is a relation between specifications, written $SP \overset{\delta}{\leadsto} SP'$, which incorporates a construction in the form of a derived signature morphism $\delta$ taking models of $SP'$ to Henkin models over the signature of $SP$. Derived signature morphisms define the types and constants in one signature by giving terms over another signature, and this corresponds directly to the code in an ML functor body. It follows that the result of a complete chain of constructive refinements is a Henkin model, corresponding to a modular ML program, which is a solution to the original programming task. We give an extended example of constructive data refinement in the context of exact real number computation, and show that it is not a (constructive) logical refinement (Sect. 5).

Some recent accounts of data refinement in typed lambda calculus have employed variants of logical relations that are related to pre-logical relations, for instance [KOPTT97]. Our inclusion of a constructive element in the relation is new, and our example appears to be the first non-trivial concrete example of data refinement in the lambda calculus literature.

The idea of constructive pre-logical refinement comes from the world of algebraic specifications, where it is called abstractor implementation [ST88] or behavioural implementation [ST97]. This paper is an attempt to explain this idea in lambda calculus terms, since it is a substantial improvement on current accounts of data refinement in that context. One novelty with respect to existing work on abstractor implementations concerns the connection with pre-logical
relations, which generalizes Schoett’s characterization of observational equivalence via correspondences and makes a bridge with work on data refinement in lambda calculus based on logical relations. Another novelty concerns the use of derived signature morphisms in the typed lambda calculus for defining constructions. In order for abstractor implementations to compose, constructions are required to preserve observational equivalence, a property known as stability [Sch87]. This requirement is normally imposed as an assumption on the language used for defining constructions, which is left unspecified. Here, stability follows easily from the Basic Lemma of pre-logical relations. Finally, the example in Sect. 5 goes considerably beyond the simple examples of refinement of data representation that have been considered previously.

2 Preliminaries: syntax and semantics

For the sake of simplicity of the exposition we restrict attention to \( \lambda^- \), the simply-typed lambda calculus having \( ! \) as its only type constructor.

**Definition 2.1.** The set of types over a set \( B \) of base types (or type constants) is given by the grammar \( \sigma ::= b \mid \sigma \to \sigma \) where \( b \) ranges over \( B \). A signature \( \Sigma \) consists of a set \( B \) of type constants and a collection \( C \) of typed term constants \( c : \sigma \). \( \text{Types}(\Sigma) \) denotes the set of types over \( B \).

In a \( \Sigma \)-context \( \Gamma = x_1 : \sigma_1, \ldots, x_n : \sigma_n \), we require that \( x_i \neq x_j \) for all \( 1 \leq i < j \leq n \) and \( \sigma_i \in \text{Types}(\Sigma) \) for all \( 1 \leq i \leq n \). \( \Sigma \)-terms are given by the grammar \( M ::= x \mid c \mid \lambda x : \sigma. M \mid MM \) where \( x \) ranges over variables and \( c \) over term constants. The usual typing rules associate each well-formed term \( M \) in context \( \Gamma \) with a type \( \Gamma \vdash M : \sigma \) (or \( \Gamma \vdash_{\Sigma} M : \sigma \) when we need to make \( \Sigma \) explicit). If \( \Gamma \) is empty then we write simply \( \vdash M : \sigma \) or \( \vdash_{\Sigma} M : \sigma \).

**Definition 2.2.** A \( \Sigma \)-Henkin model \( A \) consists of:

- a carrier set \([\sigma]^A\) for each \( \sigma \in \text{Types}(\Sigma) \);
- a function \( \text{App}^A : [\sigma \to \tau]^A \to [\sigma]^A \to [\tau]^A \) for each \( \sigma, \tau \in \text{Types}(\Sigma) \);
- an element \([c]^A \in [\sigma]^A\) for each term constant \( c : \sigma \) in \( \Sigma \); and
- elements \( K^A_{\sigma, \tau} \in [\sigma \to (\tau \to \sigma)]^A \) and \( S^A_{\sigma, \tau, \rho} \in [(\rho \to \sigma \to \tau) \to (\rho \to \sigma) \to \rho \to \tau]^A \) for each \( \rho, \sigma, \tau \in \text{Types}(\Sigma) \)

such that

- \( K^A_{\sigma, \tau} x y = x \) and \( S^A_{\sigma, \tau, \rho} x y z = (x z)(y z) \); and
- (extensionality) if \( \text{App}^A f x = \text{App}^A g x \) for every \( x \in [\sigma]^A \), then \( f = g \).

The class of all \( \Sigma \)-Henkin models is denoted \( \text{Mod}(\Sigma) \).

Term constants of functional type are interpreted as total functions. Allowing partial functions does not seem to introduce problems, but we have not checked the details. Moreover, the use of Henkin models in this paper is not essential; the definitions and results in [HS99] that we will need later also apply to non-extensional models, for instance combinatory algebras.
A $\Gamma$-environment $\eta$ on a Henkin model $A$ assigns elements of $A$ to variables, with $\eta(x) \in [[\sigma]]^A$ for $x : \sigma$ in $\Gamma$. A $\Sigma$-term $\Gamma \vdash M : \sigma$ is interpreted in $A$ under a $\Gamma$-environment $\eta$ in the usual way with $\lambda$-abstraction interpreted via translation to combinators, written $[[\Gamma \vdash M : \sigma]]^A_\eta$, and this is an element of $[[\sigma]]^A$. If $M$ is closed then we write simply $[ [ M : \sigma ] ]^A$.

We can allow terms to contain the fixed-point combinator $Y$ (viewed as a term constant). To interpret such terms in a Henkin model $A$, we need to additionally require elements $Y^A_\sigma \in [[(\sigma \to \sigma) \to \sigma]]^A$ for each $\sigma \in \text{Type}(\Sigma)$ such that $f (Y^A_\sigma f) = Y^A_\sigma f$. We will assume that this additional structure is present whenever we consider such terms.

**Definition 2.3.** A logical relation $R$ over $\Sigma$-Henkin models $A$ and $B$ is a family of relations \( \{ R^\sigma \subseteq [[\sigma]]^A \times [[\sigma]]^B \}_{\sigma \in \text{Types}(\Sigma)} \) such that:

- $R^\sigma_{-\tau}(f, g)$ iff $\forall a \in [[\sigma]]^A \forall b \in [[\sigma]]^B R^\sigma(a, b) \Rightarrow R^\sigma(App_A f a, App_B g b)$.
- $R^\sigma([ [ c ]]^A, [ [ c ] ]^B)$ for every term constant $c : \sigma$ in $\Sigma$.

**Definition 2.4.** If $\Gamma \vdash \Sigma M : \sigma$ and $\Gamma \vdash \Sigma M' : \sigma$ then $\forall \Gamma. M =_\sigma M'$ is a $\Sigma$-equation. The subscript $\sigma$ is omitted when it is obvious. A $\Sigma$-Henkin model $A$ satisfies a $\Sigma$-equation $\forall \Gamma. M =_\sigma M'$ if $[[\Gamma \vdash M : \sigma]]^A_\eta = [[\Gamma \vdash M' : \sigma]]^A_\eta$ for all $\Gamma$-environments $\eta$. It is easy to add connectives and quantifiers, giving sentences of predicate logic with equality. A specification $SP$ consists of a signature $\Sigma$ and a set $\Phi$ of $\Sigma$-sentences. Then $\text{Sig}(SP) = \Sigma$, and $\text{Mod}(SP)$ (the models of $SP$) is the class of all $\Sigma$-Henkin models satisfying all the sentences in $\Phi$.

## 3 Data refinement

We begin with an analysis of the failure of composition of logical relations and its impact on composition of logical refinements.

**Example 3.1.** Let $\Sigma$ contain two type constants, $b$ and $b'$, and no term constants. Consider $\Sigma$-Henkin models $A, B, C$ which interpret $b$ and $b'$ as follows, and interpret function types using full set-theoretic function spaces: $[[b]]^A = \{ * \} = [[b']]^A$; $[[b]]^B = \{ \circ, \bullet \}$; $[[b]]^C = \{ \circ, \bullet \} = [[b']]^C$. Let $R$ be the logical relation over $A$ and $B$ induced by $R^b = \{ (*, *, *) \}$ and $R^{b'} = \{ (*, \circ, *) \}$ and let $S$ be the logical relation over $B$ and $C$ induced by $S^b = \{ (*, \circ, *) \}$ and $S^{b'} = \{ (\circ, \circ, \bullet) \}$. $S \circ R$ is not a logical relation because it does not relate the identity function in $[[b]]^A \to [[b']]^A$ to the identity function in $[[b]]^C \to [[b']]^C$. The problem is that the only two functions in $[[b]]^B \to [[b']]^B$ are $* \mapsto \circ$ and $* \mapsto \bullet$, and $S$ does not relate these to the identity in $C$. \( \square \)

This simple example shows that we may have logical refinements $A \overset{S}{\rightarrow} B$ and $B \overset{S}{\rightarrow} C$ (where we take $OBS = \emptyset$ in both cases), where $S \circ R$ is not a logical relation and so cannot act as witness to $A \overset{S}{\rightarrow} C$.

One possible solution might be to construct the relations at higher types from the composite relations at base types. This works if $\Sigma$ contains only first-order term constants (guaranteeing that the restriction to base types lifts to a logical
relation) and if \( \text{OBS} \) contains only base types (guaranteeing that the resulting logical relation is the identity relation for each \( \sigma \in \text{OBS} \)). The following example shows how this idea fails in the presence of second-order term constants.

**Example 3.2.** In the previous example, add a type constant \( \text{bool} \) and a term constant \( c : (b \to b') \to \text{bool} \) to \( \Sigma \). Let \( [\text{bool}]^A = [\text{bool}]^B = [\text{bool}]^C = \{\text{true}, \text{false}\} \) and take \( R^\text{bool} \) and \( S^\text{bool} \) to be the identity. In each model, let the interpretation of \( c \) take constant functions to \( \text{true} \) and all other functions to \( \text{false} \). The resulting \( R \) and \( S \) are logical relations. As before, \( S \circ R \) is not a logical relation but now the restriction of \( S \circ R \) to base types cannot be lifted to a logical relation either: this would relate the identity function in \( [b]^A \to [b']^A \) (which is a constant function) to every function in \( [b]^C \to [b']^C \), but then the constant function in \( A \) would be related to non-constant functions in \( C \), and so \( [c]^A \) could not be related to \( [c]^C \), otherwise \( \text{true} \) would be related to \( \text{false} \).

These two examples show that certain ways of composing the logical relations witnessing \( A \rightsquigarrow B \) and \( B \rightsquigarrow C \) do not yield a logical relation witnessing \( A \rightsquigarrow C \). Such a witness may exist, however, and in the above example it does. For \( \text{OBS} = \emptyset \), the full relation suffices; for \( \text{OBS} = \{\text{bool}\} \), the full relation on \( b \) together with the empty relation on \( b' \) and the identity on \( \text{bool} \) lifts to a logical relation. But if we add constants \( b_1, b_2 : b \) and \( b_1', b_2' : b' \) with \( [b_1]^A = [b_2]^A = [b_1']^A = [b_2']^A = \ast \), \( [b_1]^C = [b_1']^C = \circ \) and \( [b_2]^C = [b_2']^C = \bullet \) then there is no logical relation over \( A \) and \( C \) which is the identity on \( \text{bool} \) so \( A \nmid C \) for \( \text{OBS} = \{\text{bool}\} \).

The following proposition summarizes the situation.

**Proposition 3.3.** \( A \rightsquigarrow B \) and \( B \rightsquigarrow C \) does not in general imply \( A \rightsquigarrow C \). \( \square \)

Ultimately, the justification for the definition of logical refinement lies in the notion of observational equivalence, in terms of which the underlying concept of data refinement is formulated.

**Definition 3.4.** Let \( A \) and \( B \) be \( \Sigma \)-Henkin models and let \( \text{OBS} \subseteq \text{Types}(\Sigma) \). Then \( A \) is observationally equivalent to \( B \) with respect to \( \text{OBS} \), written \( A \equiv_{\text{OBS}} B \), if for any two closed \( \Sigma \)-terms \( M, N : \sigma \) for \( \sigma \in \text{OBS} \), \( [M : \sigma]^A = [N : \sigma]^A \) iff \( [M : \sigma]^B = [N : \sigma]^B \).

It is usual to take \( \text{OBS} \) to be the “built-in” types for which equality is decidable, for instance \( \text{bool} \) and/or \( \text{nat} \). Then \( A \) and \( B \) are observationally equivalent iff it is not possible to distinguish between them by performing computational experiments. Note that \( \text{OBS} \subseteq \text{OBS}' \) implies \( \equiv_{\text{OBS}} \supseteq \equiv_{\text{OBS}'} \).

For \( \text{OBS} = \{\text{nat}\} \), the connection between logical refinement and observational equivalence is given by Mitchell’s representation independence theorem.

**Theorem 3.5 ([Mit96]).** Let \( \Sigma \) be a signature that includes a type constant \( \text{nat} \), and let \( A \) and \( B \) be \( \Sigma \)-Henkin models, with \( [\text{nat}]^A = [\text{nat}]^B = \text{N} \). If there is a logical relation \( R \) over \( A \) and \( B \) with \( R^{\text{nat}} \) the identity relation on natural numbers, then \( A \equiv_{(\text{nat})} B \). Conversely, if \( A \equiv_{(\text{nat})} B \), \( \Sigma \) provides a closed term for each element of \( \text{N} \), and \( \Sigma \) contains only first-order term constants, then there is a logical relation \( R \) over \( A \) and \( B \) with \( R^{\text{nat}} \) the identity relation. \( \square \)
The restriction to signatures with first-order term constants in the second part of the theorem is necessary, and this is the key to the incompleteness of logical refinements as a proof method and the problem with composability of logical refinements. If $A \rightsquigarrow B \rightsquigarrow C$ then $A \equiv_{OBS} B \equiv_{OBS} C$, and so $A \equiv_{OBS} C$ since $\equiv_{OBS}$ is an equivalence relation. But then it follows that $A \rightsquigarrow C$ only for signatures without higher-order term constants.

An improved version of the above theorem, without the restriction to first-order signatures, holds if logical relations are replaced by pre-logical relations.

Definition 3.6 ([HS99]). A pre-logical relation $\mathcal{R}$ over $\Sigma$-Henkin models $A$ and $B$ is a family of relations $\{R^\sigma \subseteq \llbracket \sigma \rrbracket^A \times \llbracket \sigma \rrbracket^B\}_{\sigma \in \text{Types}(\Sigma)}$ such that:

- If $R^\sigma(f,g)$ then $\forall a \in \llbracket \sigma \rrbracket^A. \forall b \in \llbracket \sigma \rrbracket^B. R^\sigma(a,b) \Rightarrow R^\sigma(\text{App}_A f a, \text{App}_B g b)$.
- $R^\sigma([c]^A, [c]^B)$ for every term constant $c : \sigma$ in $\Sigma$.
- $R(S^\rho_A, S^\rho_B)$ and $R(K^\rho_A, K^\rho_B)$ for all $\rho, \sigma, \tau \in \text{Types}(\Sigma)$.

Theorem 3.7 ([HS99]). Let $A$ and $B$ be $\Sigma$-Henkin models and let $\llbracket \text{OBS} \rrbracket \subseteq \text{Types}(\Sigma)$. Then $A \equiv_{OBS} B$ iff there exists a pre-logical relation over $A$ and $B$ which is a partial injection on $\text{OBS}$.

This suggests the following. (We switch to a notation that makes the set of observable types explicit.)

Definition 3.8. Let $A$ and $B$ be $\Sigma$-Henkin models and $\llbracket \text{OBS} \rrbracket \subseteq \text{Types}(\Sigma)$. Then $B$ is a pre-logical refinement of $A$, written $A \overset{\text{OBS}}{\rightsquigarrow} B$, if there is a pre-logical relation $\mathcal{R}$ over $A$ and $B$ such that $R^\sigma$ is a partial injection for each $\sigma \in \text{OBS}$.

We phrase this as a definition, rather than as a proof method for the underlying notion of data refinement, in contrast to logical refinements. As a proof method it is sound and complete, and therefore equivalent to this underlying notion.

Pre-logical relations compose [HS99], so pre-logical refinements compose, and this explains why stepwise refinement is sound. Another explanation goes via Theorem 3.7: $A \overset{\text{OBS}}{\rightsquigarrow} B \overset{\text{OBS}}{\rightsquigarrow} C \Rightarrow A \equiv_{OBS} B \equiv_{OBS} C \Rightarrow A \equiv_{OBS} C \Rightarrow A \overset{\text{OBS}}{\rightsquigarrow} C$. The set of observable types need not be the same in both steps, as the following result spells out.

Proposition 3.9. If $A \overset{\text{OBS}}{\rightsquigarrow} B$ and $B \overset{\text{OBS}}{\rightsquigarrow} C$ then $A \overset{\text{OBS}}{\rightsquigarrow} C$ provided $\llbracket \text{OBS} \rrbracket \subseteq \llbracket \text{OBS}' \rrbracket$.

The definition of observational equivalence may be extended to allow experiments to include the fixed-point combinator by requiring Henkin models to include elements $Y^\sigma_A \in \llbracket \sigma \rightarrow \sigma \rrbracket^A$ for each $\sigma \in \text{Types}(\Sigma)$ as indicated above. Theorem 3.7 still holds provided pre-logical relations are required to relate $Y^\sigma_A$ with $Y^\sigma_B$ for all $\sigma$.

4 Constructive data refinement

Pre-logical refinement, like logical refinement, is a symmetric relation. This does not fit the intuition that refinement is about going from an abstract, high-level
description of a program to a concrete, more detailed description. There are at least two basic defects of the notion of pre-logical refinement of which the symmetry of the relation is merely a symptom.

First, it is a relation between Henkin models. The intuition behind stepwise refinement suggests that it should be rather a relation between descriptions of Henkin models, i.e. between specifications. The original specification of a problem rarely determines a single permissible behaviour: some of the details of the behaviour are normally left open to the implementor. So at this stage one starts with an assortment of models, corresponding to all the possible choices of behaviours. (Some of these will be isomorphic to one another, given a suitable notion of isomorphism, but if the specification permits more than one externally-visible behaviour then there will be non-isomorphic models.) The final program, on the other hand, corresponds to a single Henkin model. So the refinement process involves not just replacement of abstract data representations by more concrete ones, but also selection between permitted behaviours.

Definition 4.1. Let \( SP \) and \( SP' \) be specifications with \( \Sigma = \text{Sig}(SP) = \text{Sig}(SP') \) and \( OBS \subseteq \text{Types}(\Sigma) \). Then \( SP' \) is a pre-logical refinement of \( SP \), written \( SP \overset{\text{OBS}}{\leadsto} SP' \), if for any \( B \in \text{Mod}(SP') \) there is some \( A \in \text{Mod}(SP) \) with a pre-logical relation \( R \) over \( A \) and \( B \) such that \( R^\sigma \) is a partial injection for each \( \sigma \in OBS \).

Second, the idea that refinement is a reduction of one as-yet-unsolved problem to another is not explicit. Intuitively, each refinement step reduces the current problem to a smaller problem, such that any solution to the smaller problem gives rise to a solution to the original problem. In pre-logical refinement of specifications, one models this by having the successive specifications accumulate more and more details arising from successive design decisions. Some parts become fully determined, and remain unchanged as a part of the specification until the final program is obtained. The parts that are not yet fully determined correspond to the unsolved parts of the original problem. (To avoid clutter, we omit the \( OBS \) decorations in the following diagrams.)

It is much cleaner to separate the finished parts from the specification, proceeding with the development of the unresolved parts only, giving

\[
\begin{align*}
SP_0 & \leadsto SP_1 \leadsto \cdots \leadsto SP_n = \text{DONE} \\
& \kappa_1 \kappa_2 \kappa_3 \cdots \kappa_n
\end{align*}
\]
where DONE is a specification having a ready realisation (e.g. a specification of the built-ins of the programming language in use). The finished parts \( \kappa_1, \ldots, \kappa_n \) are constructions extending any solution (model) of a reduced problem (specification) to a solution of the previous problem, and so we will refer to this relation as constructive data refinement. The signatures of successive specifications may be different, in contrast to the earlier refinement relations.

Constructive data refinement will be defined below. As constructions we will take “\( \delta \)-reducts” of \( \Sigma' \)-Henkin models induced by “derived signature morphisms” \( \delta : \Sigma \rightarrow \Sigma' \), where \( \Sigma \) and \( \Sigma' \) are the signatures before and after refinement, respectively. This amounts to giving an interpretation of the type constants and term constants in \( \Sigma \) as types and terms over \( \Sigma' \).

**Definition 4.2.** Let \( \Sigma \) and \( \Sigma' \) be signatures. A derived signature morphism \( \delta : \Sigma \rightarrow \Sigma' \) consists of:

- a mapping from base types in \( \Sigma \) to types over \( \Sigma' \): for every base type \( b \) in \( \Sigma \), \( \delta(b) \in \text{Types}(\Sigma') \). This induces a mapping (also called \( \delta \)) from \( \text{Types}(\Sigma) \) to \( \text{Types}(\Sigma') \), using \( \delta(\sigma \rightarrow \tau) = \delta(\sigma) \rightarrow \delta(\tau) \).

- a type-preserving mapping from term constants in \( \Sigma \) to closed terms over \( \Sigma' \): for every constant \( \sigma \) in \( \Sigma \), \( \delta_{\Sigma'}(\sigma) : \delta(\sigma) \).

This induces a mapping (also called \( \delta \)) from terms over \( \Sigma \) to terms over \( \Sigma' \), using \( \delta(x) = x \), \( \delta(\lambda x.\sigma. M) = \lambda x.\delta(\sigma).\delta(M) \), \( \delta(M \cdot M') = \delta(M) \cdot \delta(M') \), and (if we are using the \( Y \) combinator) \( \delta(Y) = Y \). Composition is obvious.

**Proposition 4.3.** If \( \delta : \Sigma \rightarrow \Sigma' \) and \( \Gamma \triangleright_{\Sigma} M : \sigma \) then \( \delta(\Gamma) \triangleright_{\Sigma'} \delta(M) : \delta(\sigma) \) where \( \delta(x_1;\sigma_1, \ldots, x_n;\sigma_n) = x_1;\delta(\sigma_1), \ldots, x_n;\delta(\sigma_n) \).

A derived signature morphism corresponds exactly to a functor in ML terminology, or a parameterised program [Gog84]: the functor parameter is a \( \Sigma' \)-Henkin model, and the functor body contains code which defines the components of \( \Sigma \) using the components of \( \Sigma' \). If the fixed-point combinator is available then this code may involve recursive functions. (Recursively-defined types are not allowed since we are working in \( \lambda^- \), but see Sect. 6.)

The semantics of these programs as functions on Henkin models is given by the notion of \( \delta \)-reduct.

**Definition 4.4.** Let \( \delta : \Sigma \rightarrow \Sigma' \) and let \( \mathcal{A}' \) be a \( \Sigma' \)-Henkin model. The \( \delta \)-reduct of \( \mathcal{A}' \) is the \( \Sigma \)-Henkin model \( \mathcal{A}'|_{\delta} \) defined as follows:

- \( [[\sigma]]_{\mathcal{A}'|_{\delta}} = [[\delta(\sigma)]]_{\mathcal{A}'} \) for each \( \sigma \in \text{Types}(\Sigma) \);

- \( \text{App}_{\mathcal{A}'|_{\delta}}^{\sigma,\tau} = \text{App}_{\mathcal{A}'}^{\delta(\sigma),\delta(\tau)} \) for each \( \sigma, \tau \in \text{Types}(\Sigma) \);

- \( [[c]]_{\mathcal{A}'|_{\delta}} = [[\delta(c)]]_{\mathcal{A}'} \) for each term constant \( c : \sigma \) in \( \Sigma \); and

- \( K_{\mathcal{A}'|_{\delta}}^{\sigma,\tau} = K_{\mathcal{A}'}^{\delta(\sigma),\delta(\tau)} \) and \( S_{\mathcal{A}'|_{\delta}}^{\rho,\sigma,\tau} = S_{\mathcal{A}'}^{\delta(\rho),\delta(\sigma),\delta(\tau)} \) and (if we are using the \( Y \) combinator) \( Y_{\mathcal{A}'|_{\delta}}^{\sigma} = Y_{\mathcal{A}'}^{\delta(\sigma)} \) for each \( \rho, \sigma, \tau \in \text{Types}(\Sigma) \).

**Proposition 4.5.** \( [[\Gamma \triangleright_{\Sigma} M : \sigma]]_{\eta} = [[\delta(\Gamma) \triangleright_{\Sigma'} \delta(M) : \delta(\sigma)]]_{\eta} \).
\(\Sigma\)-Henkin models and pre-logical relations between such models form a category \(\text{Mod}(\Sigma)\). The following property is intimately related to the concept of stability in [Sch87].

**Proposition 4.6 (Stability).** For any \(\delta : \Sigma \rightarrow \Sigma'\), the mapping \(\cdot|_{\delta}\) extends to a functor \(\cdot|_{\delta} : \text{Mod}(\Sigma') \rightarrow \text{Mod}(\Sigma)\). If a pre-logical relation \(R'\) in \(\text{Mod}(\Sigma')\) is a partial injection on \(OBS' \subseteq \text{Types}(\Sigma')\), then \(R'|_{\delta}\) is a partial injection on \(\delta^{-1}(OBS')\). Thus \(A'|_{OBS'} : B' \Rightarrow \) implies \(A'|_{\delta} : OBS' |_{\delta} \Rightarrow \) for any \(OBS \subseteq \text{Types}(\Sigma)\) such that \(\delta(OBS) \subseteq OBS'\).

**Proof.** Take \((R|_{\delta})^\sigma = R^{\delta(\sigma)}\). It follows from the Basic Lemma for pre-logical relations (see [HS99]) that this yields a pre-logical relation. \(\Box\)

Now we are ready to give a formal definition of constructive data refinement.

**Definition 4.7.** Let \(SP\) and \(SP'\) be specifications, \(\delta : \text{Sig}(SP) \rightarrow \text{Sig}(SP')\) be a derived signature morphism, and let \(OBS \subseteq \text{Types}(\text{Sig}(SP))\). Then \(SP'\) is a constructive pre-logical refinement of \(SP\) via \(\delta\), written \(SP \overset{OBS}{\underset{\delta}{\Rightarrow}} SP'\), if for any \(B \in \text{Mod}(SP')\) there is some \(A \in \text{Mod}(SP)\) with a pre-logical relation \(R\) over \(A\) and \(B|_{\delta}\) such that \(R^\sigma\) is a partial injection for each \(\sigma \in OBS\).

It is easy to modify this definition to give a notion of constructive logical refinement, written \(\Rightarrow\). The correspondence between derived signature morphisms as defined above and ML functors justifies the use of the word “constructive”. In Sect. 5 below we give an example of constructive pre-logical refinement and show that it is not a constructive logical refinement.

Constructive pre-logical refinements compose via the composition of their underlying derived signature morphisms:

**Proposition 4.8.** If \(SP \overset{OBS}{\underset{\delta}{\Rightarrow}} SP'\) and \(SP' \overset{OBS'}{\underset{\delta'}{\Rightarrow}} SP''\) then \(SP \overset{OBS'}{\underset{\delta' \circ \delta}{\Rightarrow}} SP''\) provided \(\delta(OBS) \subseteq OBS'\). \(\Box\)

The required relationship between \(OBS\) and \(OBS'\) is just what one would expect: as refinement progresses, the successive specifications become increasingly less abstract and so the number of non-observable types tends to decrease, while the overall task of implementing \(SP\) with observable types \(OBS\) remains the same.

As suggested above, a chain of constructive refinements is complete when the original problem has been reduced to a specification \(DONE\) with a given (implemented) model \(D:\)

\[
SP_0 \overset{OBS_0}{\underset{\delta_0}{\Rightarrow}} SP_1 \overset{OBS_2}{\underset{\delta_2}{\Rightarrow}} \cdots \overset{OBS_n}{\underset{\delta_n}{\Rightarrow}} SP_n = DONE
\]

Then, by Prop. 4.8, if the condition on \(OBS_1, \ldots, OBS_n\) is satisfied, \(DONE\) is a constructive pre-logical refinement of \(SP_0\) via \(\delta_n \circ \cdots \circ \delta_2 \circ \delta_1\) with respect to \(OBS_1\); the Henkin model \(D|_{\delta_n \circ \cdots \circ \delta_2 \circ \delta_1}\) is observationally equivalent to some model of \(SP_0\) with respect to \(OBS_1\). In other words, \(\delta_n \circ \cdots \circ \delta_2 \circ \delta_1\) is a program that is a solution to the original programming task.
5 An example from real number computation

We now present an extended example of constructive data refinement in the context of exact real number computation. The point of this example is that the desired refinement can be expressed in terms of pre-logical relations, but not in terms of logical relations.

We will describe a specification \( SP \) involving real numbers and some operations on them, and a specification \( SP' \) which provides a means of implementing \( SP \) using higher-type functions. We will then present a constructive pre-logical refinement \( SP \overset{\delta}{\Rightarrow} SP' \) that captures this implementation; however, we will show that there is no constructive logical refinement \( SP \overset{\delta}{\Rightarrow} SP' \).

5.1 A specification for real number operations

The specification \( SP \) has an underlying signature \( \Sigma \) consisting of the type constants \( \text{real} \) and \( \text{bool} \) and the following term constants:

\[
\begin{align*}
0, 1 : & \text{real} \\
- : & \text{real} \to \text{real} \\
+,: & \text{real} \to \text{real} \\
\max: & \text{real} \to \text{real} \to \text{real} \\
\sup_{[0,1]} : & (\text{real} \to \text{real}) \to \text{real} \\
\text{true, false, } & \bot : \text{bool} \\
< : & \text{real} \to \text{real} \to \text{bool}
\end{align*}
\]

We declare \( \text{bool} \) (only) to be an observable type. As usual, we treat \(+, *, \max\) as infixes. One could of course consider richer signatures (e.g. with division), but the signature above has the technical advantage that all the above operations are total functions in the intended models (see below regarding the interpretation of \( \sup_{[0,1]} \)).

A class of intended models for \( SP \) may be given via some logical axioms, as follows. For \( 0, 1, -, +, * \), we take the usual axioms for a field; we also add axioms saying that the type \( \text{real} \) is totally ordered by \( \leq \), where \( t \leq u \) abbreviates the logical formula \( \exists z:\text{real}.u = t + (z * z) \). For \( \max \) and \( \sup_{[0,1]} \), we add the axioms

\[
\forall x,y:\text{real}.(x \leq y \Rightarrow \max x y = y) \land (y \leq x \Rightarrow \max x y = x)
\]

\[
\forall f : \text{real} \to \text{real}. (\exists z:\text{real}. \forall x:\text{real}. 0 \leq x \land x \leq 1 \Rightarrow f(x) \leq z) \Rightarrow \\
(\forall z:\text{real}. \sup_{[0,1]} f \leq z \Leftrightarrow \forall x:\text{real}. 0 \leq x \land x \leq 1 \Rightarrow f(x) \leq z)
\]

An important logical consequence of these axioms (which we shall use later) is the formula \( \sup_{[0,1]}(\lambda x:\text{real}.0) = 0 \).

The language we have defined is surprisingly expressive. For instance, every algebraic real number is definable by a closed term, and so any model for \( SP \) must contain a copy of at least the algebraic reals. In fact, the models we have in mind contain all the computable or recursive reals (though not every computable real is definable by a closed term).

The only purpose of including the type \( \text{bool} \) in \( SP \) is to allow us to make observations on real numbers. In general we do not expect to be able to tell when two real numbers are the same, but we can tell when they are different.
It suffices for our purposes to include the order relation $<$ in our signature. The axioms for $<$ are:

\[ \forall x, y: \text{real}. \, (\neg y \leq x) \Rightarrow x < y = \text{true} \]
\[ \forall x, y: \text{real}. \, (\neg x \leq y) \Rightarrow x < y = \text{false} \]
\[ \forall x, y: \text{real}. \, x = y \Rightarrow x < y = \bot \]

This completes the definition of $SP$.

Some brief remarks on models for $SP$ may be helpful. The full set-theoretic type structure over $\mathbb{R}$ gives a model of $SP$, though we need to assign arbitrary values to the interpretation of $\sup_{[0,1]}$ on functions $f: \mathbb{R} \to \mathbb{R}$ which are unbounded on $[0,1]$. There are also natural models in which the interpretation of $\text{real} \to \text{real}$ is constrained to include only continuous functions (see e.g. [Nor98]).

5.2 A specification for PCF computations

We now present a specification $SP'$ corresponding to the familiar functional language PCF [Plo77]. A constructive refinement $SP \overset{\delta}{\rightarrow} SP'$ for $OBS = \{ \text{bool} \}$ then amounts to a way of implementing $SP$ in PCF via a "program" $\delta$.

The signature $\Sigma'$ for $SP'$ will consist of the single type constant $\text{nat}$ and:

\[
0 : \text{nat} \quad \text{ifzero} : \text{nat} \to \text{nat} \to \text{nat} \to \text{nat} \\
\text{succ, pred} : \text{nat} \to \text{nat} \\
Y^\sigma : (\sigma \to \sigma) \to \sigma \quad (\sigma \in \text{Types}(\Sigma'))
\]

This is exactly the language for (a version of) PCF. The intention is that $\text{nat}$ stands for the lifted natural numbers, with the term $\bot \equiv Y^{\text{nat}}(\lambda z: \text{nat}. z)$ denoting the bottom element. We freely employ syntactic sugar in PCF terms where the meaning is evident.

We now wish to add axioms to ensure that any model for $SP'$ is a model of PCF in some reasonable sense. We do not know whether all the axioms below are strictly necessary for our purposes, but they correspond to a well-understood class of models of PCF. Let us write $t \downarrow$ as an abbreviation for the formula $\text{ifzero } t \ 0 \ 0 = 0$ (we may read this as "$t$ terminates"). First we have an axiom saying there is only one non-terminating element of type $\text{nat}$:

\[ \forall x: \text{nat}. \, \neg (x \downarrow) \iff x = \bot \]

For $0$ and $\text{succ}$, we take the usual first-order Peano axioms for the terminating elements. For the remaining constants, we take the axioms

\[
\begin{align*}
\text{pred } 0 &= 0 \\
\forall y, z: \text{nat}. \, \text{ifzero } 0 \ y \ z &= y \\
\forall y, z: \text{nat}. \, \text{ifzero } \bot \ y \ z &= \bot \\
\forall f : \sigma \to \sigma. \, Y^\sigma f &= f(Y^\sigma f) \\
\forall f : \sigma \to \sigma, z: \sigma. \, f \ z &= f \ z \Rightarrow Y^\sigma f \sqsubseteq_\sigma z
\end{align*}
\]

where $t \subseteq_\sigma u$ abbreviates $\forall P : \sigma \to \text{nat}. \, (P \ t \downarrow) \Rightarrow (P \ u \downarrow)$.

Note that the full set-theoretic type structure over $\mathbb{N}_\bot$ is not a model, because not every set-theoretic function $\mathbb{N}_\bot \to \mathbb{N}_\bot$ has a fixed point. However, the usual
Scott model based on CPOs (see [Plo77]) and the game models of e.g. [AJM96] do provide models of $SP'$, as do their recursive analogues. The extensional closed term model of PCF also provides a model (which in fact is isomorphic to the recursive game models).

5.3 A constructive pre-logical refinement

We now describe a constructive refinement from $SP$ to $SP'$. The basic idea is that we will represent a real number $r$ by an infinite sequence $d = d_0d_1d_2 \ldots$ of natural numbers, which in turn is represented by the function $f : N \rightarrow N$ given by $f(i) = d_i$. (More generally: in any model $B$ of $SP'$, including non-standard ones, there will be an inclusion from $N$ to $[nat]^B$; for simplicity of notation we take $N \subseteq [nat]^B$. Then we represent $d$ by any function $f \in [nat \rightarrow nat]^B$ such that $f(i) = d_i$ for all $i \in N$.) Operations on reals are then represented by higher-type operations on such functions. There are many ways to choose a suitable representation, and the differences between them do not matter much. For definiteness, we will work with sequences $d$ such that $d_i \leq 2$ for all $i \geq 2$; such a sequence will represent the real number $d_0 - d_1 + \sum_{i=2}^{\infty} 2^{1-i}(d_i - 1)$. We will use the meta-notation $\text{IsReal}(f)$ to mean that $f \in [nat \rightarrow nat]^B$ represents a real number in this way, and write $\text{Val}(f)$ to denote the real number it represents. Note that there will be many sequences representing any given real number — this is in fact an essential feature of any representation of reals for which even the most basic arithmetical operations are computable. The above choice is essentially a signed binary representation involving infinite sequences of digits $-1, 0, 1$ (coded in PCF by $0, 1, 2$ respectively).

We can make precise the idea of implementing $SP$ in terms of $SP'$ by means of a derived signature morphism $\delta : \Sigma \rightarrow \Sigma'$. For the basic types, we take

$\delta(\text{real}) = \text{nat} \rightarrow \text{nat}, \quad \delta(\text{bool}) = \text{nat}.$

Next, for each term constant $c : \sigma$ of $\Sigma$ we need to give a term $\delta(c) : \delta(\sigma)$ in $\Sigma'$. For the constants $0$ and $1$, this can be done just by choosing one particular representing sequence for these real numbers, e.g.

$\delta(0) = \lambda i: \text{nat}. \, 1, \quad \delta(1) = \lambda i: \text{nat}. \, \text{ifzero} \, i \, 2 \, 1.$

For the booleans, we take $\delta(\text{true}) = 0$, $\delta(\text{false}) = 1$ and $\delta(\bot) = \bot$. It is also straightforward to write PCF programs $\text{Minus}$, $\text{Plus}$, $\text{Times}$, $\text{Max}$, $\text{Less}$ for $\delta(-)$, $\delta(+)$, $\delta(\times)$, $\delta(\text{max})$ and $\delta(<)$ respectively. For example, we may take

$\text{Minus} = \lambda f : \text{nat} \rightarrow \text{nat}, \, i: \text{nat}.\:$

if $i = 0$ then $f(1)$ else if $i = 1$ then $f(0)$ else $2 \land f(i)$

where $\land$ implements truncated subtraction. In any model $B$, this satisfies the following condition (which should be understood as a meta-level assertion):

$\forall f \in [\text{nat} \rightarrow \text{nat}]^B. \, \text{IsReal}(f) \Rightarrow \text{IsReal}([\text{Minus}]^B f) \land \text{Val}([\text{Minus}]^B f) = -\text{Val}(f).$
Coding details for the other operations are given e.g. in [Plu98]. What is more surprising is that the operation $sup_{[0,1]}$ can be represented in PCF by a third-order function $Sup$, by means of a clever use of higher-type recursion (a detailed account of the algorithm with code is given in [Sim98]).

**Proposition 5.1.** $SP'$ is a constructive pre-logical refinement of $SP$ via $\delta$.

**Proof sketch.** Starting from any $B \in \text{Mod}(SP')$, we will obtain a model $A \in \text{Mod}(SP)$ and a pre-logical relation $R$.

The correct definition of $A$ is slightly subtle — the whole point is that the obvious definition via a logical relation on $B$ does not work (see below). First, we embed $B$ in its chain completion $B$ via an inclusion $i$ (we omit the definition). The main purpose of this step is to throw into the model all monotone functions of type $\text{nat} \rightarrow \text{nat}$ — this ensures that in $B$ we can represent all the classical reals and not just the computable ones (cf. Section 5.4 below). One can check that if $B$ is a model of $SP'$ then so is $B$. Next we define partial equivalence relations $E^{\sigma}$ on $[\sigma]B$ for each $\sigma \in \text{Types}(\Sigma)$. For the base cases, we take

$$
E^{\text{real}}(f, g) \text{ iff IsReal}(f) \land \text{IsReal}(g) \land \text{Val}(f) = \text{Val}(g),
$$

$$
E^{\text{bool}}(x, y) \text{ iff } x = y \land x \in \{0]B, [1]B, [\bot]B\}.
$$

(The latter clause means that $E$ behaves as a partial injection for observable types.) We lift this to higher types as a binary logical relation on $B$. One can show that for each constant $c$ of $\Sigma$ we have $E(i[\delta(c)]B, i[\delta(c)]B)$.

We now construct the required model $A$ by taking $[\sigma]^A$ to be the set of equivalence classes of $E^{\sigma}$; one can check that $A$ yields a Henkin model for $SP$. Finally, we define relations $R^{\sigma}$ from $[\sigma]^A$ to $[\delta(\sigma)]B$ by $R^{\sigma}(a, b) \text{ iff } i(b) \in a$; clearly this defines a pre-logical relation $R$ as required.

**5.4 Lack of a constructive logical refinement**

We now explain why $SP'$ is not a constructive logical refinement of $SP$ via $\delta$. Intuitively, the idea is that a logical relation $R$ is completely determined once we have fixed the relation at basic types — we have no freedom of choice for higher types. For certain models $B$ of $SP'$, this means that we are forced to include in the relation $R^{\text{real} \rightarrow \text{real}}$ some highly pathological elements of $[\delta(\text{real} \rightarrow \text{real})]B$, and our PCF implementation of $sup_{[0,1]}$ will fail to work for these pathological elements. This leads to a contradiction since we require $R([sup_{[0,1]}]^A, [Sup]^B)$ for some model $A$ of $SP$.

More precisely, let us take $B$ to be some effective model of $SP'$, such as the effective Scott domain model [Plo77] or the term model for PCF. All that we really require is that the elements of $[\text{nat} \rightarrow \text{nat}]B$ correspond to just the partial recursive functions $\mathbb{N}_\bot \rightarrow \mathbb{N}_\bot$. We will show the following:

**Theorem 5.2.** There is no model $A \in \text{Mod}(SP)$ admitting a logical relation $R$ over $A$ and $B|_\delta$ which is a partial injection on $\text{bool}$.
Proof sketch. The proof of the theorem hinges on the existence of a pathological
PCF implementation of the constant zero function: that is, a term Funny :
(nat → nat) → (nat → nat) such that \( R^{\text{real} \rightarrow \text{real}}([\lambda x: \text{real}. 0]^A, [\text{Funny}]^B) \), but such that \([\text{Sup Funny}]^B = [\text{Bad}]^B\), where Bad = \( \lambda y: \text{nat}. \text{if } y < 2 \text{ then } 1 \text{ else } \bot \). Since SP entails that \( \sup_{[0,1]}(\lambda x: \text{real}. 0) = 0 \), we have \( R^{\text{real}}([0]^A, [\text{Bad}]^B) \), which can be shown to be impossible.

The idea behind Funny is based on the Kleene tree, a well-known counterex-
ample from recursion theory (see e.g. [Bee85]). Intuitively, Funny(\( f \)) gives 0 whenever \( f \) represents a recursive real number but diverges for certain non-
recursive reals.

Notice how the pre-logical relation \( R \) in the proof of Proposition 5.1 avoids
this problem: the interpretation of Funny in \( B \) is not included in the partial
equivalence relation \( E^{\text{real} \rightarrow \text{real}} \), since the model contains representations of non-
recursive reals on which Funny diverges.

The above example is robust in the sense that it is not just a feature of the
particular implementation \( \text{Sup} \) we have chosen — it can be shown that there is
no PCF program \( \text{Sup} \) that computes suprema for all relevant functions including
Funny. Indeed, we believe that the above theorem should hold for all possible
representations of the reals and all choices of the terms \( (c) \): the only condition
on \( \delta \) we require is that \( \delta(\text{real}) = \text{nat} \rightarrow \text{nat} \).

6 Conclusion

The main purpose of this paper was to introduce the notion of constructive
pre-logical refinement and explain how it relates to the usual account of data
refinement for typed lambda calculus in terms of logical relations. In a nutshell,
the relationship is that for data refinement logical relations work only because
they are a special case of pre-logical relations, where the additional requirement
imposed by logical relations is more of a hindrance than a help.

There are many directions in which this approach could be developed.
In Sect. 4 we considered linear chains of refinement steps. Decomposition of
implementation tasks into separate subtasks can be modelled using construc-
tions that take \( n \)-tuples of Henkin models as arguments, giving tree-shaped
refinement diagrams. In particular, consider \( \delta : \Sigma \rightarrow (\Sigma_1' + \ldots + \Sigma_n') \), where
\( \Sigma_1' + \ldots + \Sigma_n' \) is a coproduct of the signatures \( \Sigma_1', \ldots, \Sigma_n' \). This induces the reduct
\( |\delta : \text{Mod}(\Sigma_1' + \ldots + \Sigma_n') \rightarrow \text{Mod}(\Sigma) \). However, this does not give an \( n \)-ary construction, since \( \text{Mod}(\Sigma_1') \times \ldots \times \text{Mod}(\Sigma_n') \) do not coincide
even up to isomorphism; in other words, higher-order models do not amalgamate
unambiguously. However, they weakly amalgamate: there is a standard (injec-
tive) construction that maps \( \text{Mod}(\Sigma_1') \times \ldots \times \text{Mod}(\Sigma_n') \) into \( \text{Mod}(\Sigma_1' + \ldots + \Sigma_n') \)
(e.g. by taking full function spaces for extra “mixed” function types). Composing
this with \( |\delta \), we obtain a function from \( \text{Mod}(\Sigma_1') \times \ldots \times \text{Mod}(\Sigma_n') \) to \( \text{Mod}(\Sigma) \)
as required. This still ignores one important aspect of development, namely the
possibility of mutual dependencies between subtasks. One solution, discussed
thoroughly in [SST92], is to use specifications of parametric models in the development process; the same ideas should apply here, but the technical implications of using higher-order models are yet to be worked out.

This paper presents a global view of specifications and their refinement: constructions are required to work on the “whole system” (represented as a model of the implementing specification) and produce a whole system (represented as a model of the implemented specification). Good practice suggests that there should be a way to make the refinement steps “local” — that is, to use only part of the system built so far to implement some remaining parts of the requirements specification, and then add the result to the whole system built so far. Details will be provided in a longer version of the paper.

In this paper we have focused on $\lambda^-$ only. But of course, less elementary type structures are also of great importance in software development using data refinement. One can consider inductive/coinductive datatypes, or more generally recursive types as in ML, or impredicative types as in Girard/Reynold’s System F. For instance exact real numbers as in Sect. 5 are often implemented as streams for efficiency reasons, also in purely functional contexts, and abstract data types can be understood in the context of existential types. Notions of logical relations, appropriate for each of these type disciplines, have been proposed in the literature: see e.g. [Alt98] for inductive/coinductive types and [MM85] for System F. In order to accommodate data refinement involving such datatypes we need to introduce corresponding notions of pre-logical relation. As pointed out in [HS99], there is a standard methodology here: simply require the interpretations of the “relevant” constants in the two structures to be related. Despite its simplicity, this methodology is extremely rewarding, and it allows to harvest serendipitous results also in related areas. A case in point is offered by PER models of System F, where the extra latitude and flexibility given by defining the exponential PER pre-logically allows for a number of possibly novel natural model constructions. Finally, a notion of pre-logical relation for System F would raise the intriguing question of the relationship between this framework and the one in [Han99], where data refinements in the style of [ST88] are translated into System F using existential types.
