Current Project

Current neuropsychological tools used to assess social cognition have:
1) Limited use in clinical settings.
2) Do not assess the different aspects of social cognition within the same test.

The objective of this project was to validate a novel measure of social cognitive functioning called the Edinburgh Social Cognition Test (ESCoT) using adults with ASD.

The ESCoT consists of ten dynamic, animated scenarios that are all self-contained narratives that depict an array of interactions.

It measures Cognitive Theory of Mind (ToM) and Affective ToM[1] and Interpersonal and Intrapersonal Understanding of Social Norms.

ESCot Questions

Cognitive ToM
- What is X thinking?

Affective ToM
- How does X feel at the end of the animation?

Interpersonal Understanding of Social Norms
- Did X behave as other people should behave?

Intrapersonal Understanding of Social Norms (Self-Reference)
- Would you have acted the same as X in the animation?

All questions are scored on a 0 – 3 point graded system. Participants can score a maximum of 30 in each component and a total of 120.

Results

A MANOVA was used to compare performance on each of the four components of the ESCoT.

The multivariate result was significant, V = .40, F(4, 52) = 8.97, p < .001, ηp2 = .408, indicating differential performance on the ESCoT between the two groups.

Bayesian analyses indicated that there is extreme evidence for the alternative hypotheses in the Cognitive ToM and Interpersonal Understanding of Social Norms components.

Evidence for a significant difference between the groups in Affective ToM was strong and moderate for Intrapersonal Understanding of Social Norms.

These results suggest that the ESCoT is a sensitive measure of social cognition. It is hoped that the ESCoT will be used as a tool to assess social abilities in healthy and clinical populations.

Discussion

The results demonstrated that the ASD group were impaired in all components of the ESCoT compared to neurotypicals.

Bayesian analysis indicated that there is extreme evidence for the alternative hypotheses in the Cognitive ToM and Interpersonal Understanding of Social Norms components.

Evidence for a significant difference between the groups in Affective ToM was strong and moderate for Intrapersonal Understanding of Social Norms.

These results suggest that the ESCoT is a sensitive measure of social cognition. It is hoped that the ESCoT will be used as a tool to assess social abilities in healthy and clinical populations.
