Abstract

Folk narratives are a valuable resource for humanities and social science researchers. This paper focuses on automatically recognizing folk narrative genres, such as urban legends, fairy tales, jokes and riddles. We explore the effectiveness of lexical, structural, stylistic and domain specific features. We find that it is possible to obtain a good performance using only shallow features. As dataset for our experiments we used the Dutch Folktale database, containing narratives from the 16th century until now.

1 Introduction

Folk narratives are an integral part of cultural heritage and a valuable resource for historical and contemporary comparative folk narrative studies. They reflect moral values and beliefs, and identities of groups and individuals over time (Meder, 2010). In addition, folk narratives can be studied to understand variability in transmission of narratives over time.

Recently, much interest has arisen to increase the digitalization of folk narratives (e.g. Meder (2010), La Barre and Tilley (2012), Abello et al. (2012)). In addition, natural language processing methods have been applied to folk narrative data. For example, fairy tales are an interesting resource for sentiment analysis (e.g. Mohammad (2011), Alm et al. (2005)) and methods have been explored to identify similar fairy tales (Lobo and de Matos, 2010), jokes (Friedland and Allan, 2008) and urban legends (Grundkiewicz and Gralinski, 2011).

Folk narratives span a wide range of genres and in this paper we present work on identifying these genres. We automatically classify folk narratives as legend, saint’s legend, fairy tale, urban legend, personal narrative, riddle, situation puzzle, joke or song. Being able to automatically classify these genres will improve accessibility of narratives (e.g. filtering search results by genre) and test to what extent these genres are distinguishable from each other. Most of the genres are not well defined, and researchers currently use crude heuristics or intuition to assign the genres.

Text genre classification is a well-studied problem and good performance has been obtained using surface cues (Kessler et al., 1997). Effective features include bag of words, POS patterns, text statistics (Finn and Kushmerick, 2006), and character n-grams (Kanaris and Stamatatos (2007), Sharoff et al. (2010)).

Finn and Kushmerick (2006) argued that genre classifiers should be reusable across multiple topics. A classifier for folk narrative genres should also be reusable across multiple topics, or in particular across story types¹. For example, a narrative such as Red Riding Hood should not be classified as a fairy tale because it matches a story type in the training set, but because it has characteristics of a fairy tale in general. This allows us to distinguish between particular genres, instead of just recognizing variants of the same story. In addition, this is desirable, since variants of a story type such as Red Riding Hood can appear in other genres as well, such as jokes and riddles.

¹Stories are classified under the same type when they have similar plots.
Most of the research on genre classification focused on classification of text and web genres. To the best of our knowledge, we are the first to automatically classify folk narrative genres. Our dataset contains folk narratives ranging from the 16th century until now. We first give an overview of the dataset and the folk narrative genres. We then describe the experiments, discuss the results and suggest future work.

2 Dataset

2.1 Overview

Our dataset is a large collection of folk narratives collected in the Netherlands. Although the collection contains many narratives in dialect, we restrict our focus to the narratives in standard Dutch, resulting in a total of 14,963 narratives. The narratives span a large time frame, with most of them from the 19th, 20th and 21st century, but some even dating from the 16th century as can be seen in Table 1. Each narrative has been manually annotated with metadata, such as genre, named entities, keywords and a summary.

2.2 Narrative genres

Folk narrative genres vary between cultures. Legend, myth and folktales are major genres that are present in many cultures. Bascom (1965) proposed a formal definition of these genres, based on belief, time, place, attitude and principal characters of the narratives. In this work, we restrict our attention to genres that are applicable to the Dutch folk narratives. The selected genres are described below and based on how annotators assign narratives to genres in the Dutch Folktale database.

Fairy tales are set in an unspecified time (e.g. the well-known Once upon a time . . . ) and place, and are believed not to be true. They often have a happy ending and contain magical elements. Most of the fairy tales in the collection are classified under the Aarne-Thompson-Uther classification system, which is widely used to classify and organize folk tales (Uther, 2004).

Table 1: Spread of data over time periods

Legends are situated in a known place and time, and occur in the recent past. They were regarded as non-fiction by the narrator and the audience at the time they were narrated. Although the main characters are human, legends often contain supernatural elements such as witches or ghosts.

Saint’s legends are narratives that are centered on a holy person or object. They are a popular genre in Catholic circles.

Urban legends are also referred to as contemporary legends, belief legends or FOAF (Friend Of A Friend) tales in literature. The narratives are legends situated in modern times and claimed by the narrator to have actually happened. They tell about hazardous or embarrassing situations. Many of the urban legends are classified in a type-index by Brunvand (1993).

Personal narratives are personal memories (not rooted in tradition) that happened to the narrator himself or were observed by him. Therefore, the stories are not necessarily told in the first person.

Riddles are usually short, consisting of a question and an answer. Many modern riddles function as a joke, while older riddles were more like puzzles to be solved.

Situation puzzles, also referred to as kwispels (Burger and Meder, 2006), are narrative riddle games and start with the mysterious outcome of a plot (e.g. A man orders albatross in a restaurant, eats one bite, and kills himself). The audience then needs to guess what led to this situation. The storyteller can only answer with ‘yes’ or ‘no’.

Jokes are short stories for laughter. The collection contains contemporary jokes, but also older jokes that are part of the ATU index (Uther, 2004). Older jokes are often longer, and do not necessarily contain a punchline at the end.

Songs These are songs that are part of oral tradition (contrary to pop songs). Some of them have a story component, for example, ballads that tell the story of Bluebeard.

2.3 Statistics

We divide the dataset into a training, development and test set, see Table 2. The class distribution is highly skewed, with many instances of legends and jokes, and only a small number of songs. Each story type and genre pair (for example Red Riding Hood as a fairy tale) only occurs in one of the sets. As a result, the splits are not always even across the multiple genres.

3 Experimental setup

3.1 Learning algorithm

We use an SVM with a linear kernel and L2 regularization, using the liblinear (Fan et al., 2008) and scikit-learn libraries (Pedregosa et al., 2011). We use the method by Crammer and Singer (2002) for multiclass classification, which we found to perform better than one versus all on the development data.

3.2 Features

The variety of feature types in use is described below. The number of features is listed in Table 3. The frequency counts of the features are normalized.

I Lexical features. We explore unigrams, and character n-grams (all n-grams from length 2-5) including punctuation and spaces.

II Stylistic and structural features.

POS unigrams and bigrams (CGN\textsuperscript{4} tagset) are extracted using the Frog tool (Van Den Bosch et al., 2007).

Punctuation. The number of punctuation characters such as ? and ", normalized by total number of characters.

Whitespace. A feature counting the number of empty lines, normalized by total number of lines. Included to help detect songs.

Text statistics. Document length, average and standard deviation of sentence length, number of words per sentence and length of words.

III Domain knowledge. Legends are characterized by references to places, persons etc. We therefore consider the number of automatically tagged named entities. We use the Frog tool (Van Den Bosch et al., 2007) to count the number of references to persons, organizations, location, products, events and miscellaneous named entities. Each of them is represented as a separate feature.

IV Meta data. We explore the added value of the manually annotated metadata: keywords, named entities and summary. Features were created by using the normalized frequencies of their tokens. We also added a feature for the manually annotated date (year) the story was written or told. For stories of which the date is unknown, we used the average date.

3.3 Evaluation

We evaluate the methods using precision, recall and F\textsubscript{1}-measure. Since the class distribution is highly skewed, we focus mainly on the macro average that averages across the scores of the individual classes.
4 Results

The penalty term C of the error term for SVM was set using the development set. All results reported are on the test set. We first report two baselines in Table 4, using only unigrams and character based n-grams. Results show that the character based n-grams are highly effective. This is probably because they are able to capture punctuation and endings of words, and are more robust to spelling mistakes and (historical) variations.

Next, ablation studies were performed to analyze the effectiveness of the different feature types, by leaving that particular feature type out. We experimented with and without metadata. The results without metadata are reported in Table 5. We find that only character n-grams contribute highly to the performance. Removing the other feature types almost has no effect on the performance. However, without character n-grams, the other features do have an added value to the unigram baseline (an increase in macro average of 0.50 to 0.53 in F1 score). One should note that some errors might be introduced due to mistakes by the automatic taggers for the POS tokens and the domain knowledge features (named entities), causing these features to be less effective.

The results with all features including the metadata are reported in Table 6. We find that when using all features the F1 score increases from 0.61 to 0.62. The ablation studies suggest that especially the keywords, summary and date are effective. However, overall, we find that only using character n-grams already gives a good performance. We therefore believe they are a valuable alternative against more sophisticated features.

We also find that including the date of a narrative as a feature leads to an increase from 0.614 to 0.621. This feature is effective since some genres (such as urban legends) only occur in certain time periods. Noise due to the many documents (1154 of 14963) for which the date is not known, could have affected the effectiveness of the feature.

In Table 7 the results per genre are listed for the run including all features (with metadata). The best performing genres are jokes, riddles and legends. We find that songs are always incorrectly classified, probably due to the small number of training examples. Personal narratives are also a difficult category. These narratives can be about any topic, and they do not have a standard structure. Fairy tales are often misclassified as legends. Some of the fairy tales do not contain many magical elements, and therefore look very similar to legends. In addition, the texts in our dataset are sometimes interleaved with comments that can include geographical locations, confusing the model even more.

Initially, annotators of the Dutch Folktale database were allowed to assign multiple genres. From this, we observe that many narratives were classified under multiple genres (these narratives were excluded from the dataset). This is evidence that for some narratives it is hard to assign a single genre, making it unclear what optimal performance can be achieved.
5 Conclusion

Folk narratives are a valuable resource for historical comparative folk narrative studies. In this paper we presented experiments on classifying folk narrative genres. The goal was to automatically classify narratives, dating from the 16th century until now, as legend, saint’s legend, fairy tale, urban legend, personal narrative, riddle, situation puzzle, joke or song. Character n-grams were found to be the most effective of all features. We therefore plan to explore historical texts in non standard Dutch, since character n-grams can be easily extracted from them. We also intend to explore features that help detect difficult genres and generalize across specific stories. For example, features that can detect humorous components.
