**Abstract**

Immunoologically intact BALB/c mice infected with *Leishmania mexicana* develop non-healing progressively growing lesions associated with a biased Th2 response while similarly infected IL-4Rα-deficient mice fail to develop lesions and develop a robust Th1 response. In order to determine the functional target(s) for IL-4/IL-13 inducing non-healing disease, the course of *L. mexicana* infection was monitored in mice lacking IL-4Rα expression in specific cellular compartments. A deficiency of IL-4Rα expression on macrophages/neutrophils (in LysMcreIL-4Rα−/lox animals) had minimal effect on the outcome of *L. mexicana* infection compared with control IL-4Rα+/lox mice. In contrast, CD4+ T cell specific (LckcreIL-4Rα−/lox) IL-4Rα−/− mice infected with *L. mexicana* developed small lesions, which subsequently healed in female mice, but persisted in adult male mice. While a strong Th1 response was manifest in both male and female CD4+ T cell specific IL-4Rα−/− mice infected with *L. mexicana*, induction of IL-4 was manifest in males but not females, independently of CD4+ T cell IL-4 responsiveness. Similar results were obtained using pan-T cell specific (iLckcreIL-4Rα−/lox) IL-4Rα−/− mice. Collectively these data demonstrate that upon infection with *L. mexicana*, initial lesion growth in BALB/c mice is dependent on non-T cell population(s) responsive to IL-4/IL-13 while progressive infection is dependent on CD4+ T cells responsive to IL-4.

**Introduction**

New world cutaneous leishmaniasis resulting from infection with *Leishmania mexicana* is under different genetic and immuno-regulatory controls to those controlling *L. major* infection [1]. Also, unlike *L. major*, the majority of mouse strains are susceptible to *L. mexicana* infection [2–3]. As with the other *Leishmania* species, protective immunity against *L. mexicana* is the result of a STAT-4 dependent type-1 immune response, although this can be generated independently of IL-12 [4]. While the immunological pathways resulting in non-healing *L. major* infections in susceptible BALB/c mice remain somewhat controversial, IL-4 plays the major role in promoting non-healing *L. mexicana* infections in this mouse strain [5–7]. Thus, mice lacking IL-4 develop small lesions that heal while those lacking IL-4Rα fail to develop lesions [6]. This also indicates some input from IL-13 in the non-healing response to *L. mexicana* infection as IL-4 and IL-13 receptors share the IL-4Rα sub unit [6]. However, IL-4 and IL-13 are pleiotropic cytokines and numerous cell types of both the innate and adaptive immune responses produce these cytokines as well as express their receptors.

In order to better differentiate both the cellular sources and targets of IL-4/IL-13 initiating lesion growth and facilitating progressive non-healing disease, we have previously examined parasite growth in SCID mice reconstituted with IL-4−/−, IL-4Rα−/−, or wild type splenocytes [5–6]. These studies indicated that non-lymphocyte sources of IL-4/IL-13 may contribute to early lesion growth during *L. mexicana* infection. However, the non-healing disease phenotype was dependent on a lymphocyte source from global effects in vivo, tissue specific IL-4Rα−/− mice have been produced. So far macrophage/neutrophil specific (LysMcreIL-4Rα−/lox) [8] and CD4+ T cell specific (LckcreIL-4Rα−/lox) [9] IL-4Rα−/− mice have been generated and the consequences for *L. major* infection studied. In contrast to susceptible BALB/c mice, BALB/c LysMcreIL-4Rα−/lox mice showed a significantly delayed disease progression after infection with *L. major*, concomitant with normal Th2 and type 2 antibody immune responses but with improved macrophage leishmanicidal activities [8]. These results suggest that alternatively activated macrophages were contributing to the susceptible phenotype in non-healer BALB/c mice. Furthermore T cell-specific LckcreIL-4Rα−/lox BALB/c mice infected with *L. major* were significantly...
Author Summary

Leishmania species are parasites, transmitted by sandflies which are of extensive public health importance in the tropical and subtropical regions of the world. A large number of distinct Leishmania species cause cutaneous disease and the vast majority of studies utilize the causative agent of Old World cutaneous leishmaniasis, L. major. Other species, for example, L. mexicana, are associated with quite different patterns of disease following infection of mice when compared with L. major. Thus, while susceptible BALB/c mice deficient in the ability to respond to the cytokines IL-4/IL-13 are not protected against development of cutaneous leishmaniasis caused by L. major they are totally resistant to infection with L. mexicana. Here we describe the outcome of L. mexicana infection in BALB/c mice with cell-specific deletion of the receptor for IL-4/IL-13 on macrophages/neutrophils or T helper cells. Infections develop in both mutants but lesion growth is controlled only in T cell specific knockouts and female but not male mice heal. Male but not female T cell specific knockouts maintain a strong IL-4/IL-13 response. This highlights the role of IL4/IL-13 in driving a non-healing phenotype and may in part explain why human males are more susceptible to this infection than females.

more resistant than global IL-4Rα−/− mice and developed a disease phenotype and clinical immunity similar to genetically resistant C57BL/6 mice [9]; not only showing the importance of IL-4Rα signaling via CD4+ T cells in the non-healing BALB/c phenotype but paradoxically indicating a protective role for IL-4Rα signaling in a non-CD4+ T cell population. In the present study we demonstrate that in contrast to L. major infection [8], macrophage/neutrophil signaling via IL-4Rα has minimal effect on the outcome of L. mexicana infection in BALB/c mice. In addition, unlike global IL-4Rα−/− mice infected with L. mexicana that display no lesion growth, infected CD4+ T cell specific [LckCreIL-4Rαlox/lox] IL-4Rα−/− mice initially develop lesions indicating that early susceptibility to L. mexicana is dependent on an IL-4 responsive non-CD4+ T cell population. However, subsequent lesion growth is significantly curtailed in infected CD4+ T cell specific [LckCreIL-4Rαlox/lox] IL-4Rα+/− mice compared with IL-4Rα intact mice, and a strong Th1 response generated in the presence of significant elements of Th2 activity. Despite reduced susceptibility in all CD4+ T cell specific [LckCreIL-4Rαlox/lox] IL-4Rα−/− mice, a dichotomy between the sexes was identified during L. mexicana infection and while lesions in female CD4+ T cell specific [LckCreIL-4Rαlox/lox] IL-4Rα−/− mice healed they persisted in male mice associated with elevated IL-4 production in this sex compared with females. Together, our results suggest that initial development of the L. mexicana lesion is dependent on an IL-4/IL-13 responsive non-T cell population, whilst progressive infection is dependent on CD4+ T cells responsive to IL-4.

Methods

Mouse model

LysMcreIL-4Rα−/−, LckCreIL-4Rα−/−, IL-4Rαlox/lox mice were generated and maintained as previously described [9–10]. Cell-specific gene disruption in macrophages/neutrophils or T cells was achieved through an intercross between either LysMcreIL-4Rα−/− or LckCreIL-4Rα−/− and IL-4Rαlox/lox mice. Transgene-bearing LysMcreIL-4Rα−/− and LckCreIL-4Rα−/− mice, were identified by PCR genotyping as described [9–10]. The mice were maintained under specific pathogen free conditions. Animal experiments were performed in strict accordance with the UK Home Office Animal [Scientific Procedures] Act 1986 (licence number 60/3929) with approval by the University of Strathclyde Ethical Review Panel.

L. mexicana parasites and infection

L. mexicana (MYNC/BZ/62/M379) was maintained by serial passage of amastigotes inoculated into the shaven rumps of BALB/c mice. Amastigotes for use in infections were isolated from lesions and enumerated as described below. Two sites of infection were examined and either 5×10^6 L. mexicana amastigotes in a final volume of 50μl were inoculated subcutaneously into the shaven base of the tail, or 2×10^5 L. mexicana amastigotes in a final volume of 25μl were inoculated subcutaneously into the hind footpad. 6–8 week old male or female LysMcreIL-4Rαlox/lox and LckCreIL-4Rαlox/lox mice were used in each experiment, with age and sex matched cre negative IL-4Rαlox/lox littermates used as controls. The lesion diameter was measured using a sliding gauge micrometer at weekly intervals.

Enumeration of parasites

Lesions were excised from L. mexicana infected LysMcreIL-4Rαlox/lox, LckCreIL-4Rαlox/lox and IL-4Rαlox/lox mice and disrupted through a mesh with 5mL of RPMI 1640 (Cambrex Bio Science Verviers, Belgium). The parasites were washed twice at 550g in RPMI and then enumerated using an improved Naubauerm haemocytometer. Alternatively parasite numbers were quantified by limiting dilution, as previously described [11].

Splenocyte stimulation and cytokine detection

Splenocytes were isolated from infected mice and cultured for 72 hours in 96-well plates (Corning-Costar, NY, USA) in the presence or absence of L. mexicana antigentic lysate, as previously described [6]. IFN-γ and IL-4 levels were detected in the supernatants by capture ELISA. Briefly the wells of Immulon 1B flat-bottomed microtitre plates (ThermoLabsystems, MA, USA) were coated with 50μL of 1μg ml^-1 purified anti-mouse IFN-γ capture antibody R4-6A2 (BD Biosciences, Oxford, UK) or 500ng ml^-1 IL-4 capture antibody 11B11 (BD Biosciences) in PBS (pH 9.0) overnight at 4°C. Supernatants were then added to the individual wells and either 50μL recombinant mouse IFN-γ (R&D Systems, Abington, UK) or recombinant mouse IL-4 (Genzyme, Cambridge, UK) added to individual wells in duplicate in a doubling dilution with a solution of pH 7.4 PBS supplemented with 10% v/v FCS (Harlan Sera-Lab Ltd., Crawley, UK), ranging form 20ng mL^-1 to 0.01ng mL^-1 (IFN-γ) or 2ng mL^-1 to 0.977pg mL^-1 (IL-4). The plates were then incubated for 2 hours at 37°C. The bound cytokines were incubated with either biotinylated rat anti-mouse IFN-γ monoclonal antibody XMG1.2 or biotinylated rat anti-mouse IL-4 antibody BVD6-24G2 (both BD Biosciences) and detected with either conjugated streptavidin-alkaline phosphatase or conjugated streptavidin-horseradish peroxidase (BD Biosciences). The appropriate substrate was then added to the wells, p-nitrophenyl-phosphate (Sigma-Aldrich, Poole, UK) or tetramethylbenzidine in pH 5.5 sodium acetate buffer, containing 0.0003% hydrogen peroxide (BDH, Poole, UK). Finally the plates were read at an absorbance of 405nm for IFN-γ or at 450nm for IL-4.

Detection of Leishmania mexicana specific -IgG1, -IgG2a and total IgE

L. mexicana specific-IgG1 and -IgG2a were detected in the plasma of infected mice by ELISA, as previously described [12].
Briefly, Immunol 1B flat-bottomed microtitre plates were coated with 100μL of 10μg mL⁻¹ Leishmania mexicana lysate (lysis preparation previously described [13] in PBS (pH 9.0) overnight at 4°C. Plasma samples were serially diluted in duplicate, followed by a 1 hour incubation at 37°C. Bound Leishmania specific antibodies were detected with a 1 hour incubation with horseradish peroxidase conjugated goat anti-mouse IgG1 or goat anti-mouse IgG2a (Southern Biotechnology Associates Inc., AL, USA). The substrate tetramethylbenzidine in pH 5.5 sodium acetate buffer, containing 0.0003% hydrogen peroxide, was then added to the wells and, following colour development, the reaction stopped by the addition of 10% sulphuric acid, absorbance measured at 450nm using a SOFTmax PRO (Molecular Devices, CA, USA) and the endpoint dilution was determined. Total IgE was detected in the plasma of infected mice by capture ELISA as previously described [12], using R35–72 capture IgE mAb (BD Biosciences), biotinylated rat anti-mouse IgE (Southern Biotechnology Associates Inc.)

**Flow cytometry**

Draining lymph node cells were activated for 4 hours with 50 ng mL⁻¹ PMA and 300 ng mL⁻¹ Ionomycin (both Sigma-Aldrich) along with GolgiPlug (BD Biosciences). Following stimulation, cells were harvested and washed, resuspended in FACS Buffer containing Fc Block (2.4G2 hybridoma supernatant) together with the appropriate combinations of the following antibodies: CD4-APC, CD8-PerCP or B220-FTTC (all from BD Biosciences). Intracellular cytokine staining was carried out using PE-conjugated anti-IL-4 or IFN-γ with Cytofix/Cytoperm solution (all from BD Biosciences). Data was obtained using FACSCanto (BD Bioscience) and analysed using FlowJo (Tree Star Inc., CA, USA).

**Statistical analysis**

Antibody analysis was performed using the Mann-Whitney U test and all other analysis used an unpaired Student’s t test.

**Results**

### IL-4Rα signaling via macrophages/neutrophils plays little role in the susceptibility of BALB/c mice to L. mexicana

To compare the progression of L. mexicana lesion growth in LysM⁻/⁻IL-4Rα⁻/⁻ with IL-4Rα⁻/lox littermate control and global IL-4Rα⁻/⁻ mice, animals were infected with 5 × 10⁴ amastigotes into the shaven base of the tail. While no discernible lesions were identified in infected global IL-4Rα⁻/⁻ mice, as previously demonstrated [6], rapidly growing non-healing lesions were observed in both LysM⁻/⁻IL-4Rα⁻/lox and IL-4Rα⁻/lox mice (Figure 1A). Parasite burdens were also similar in LysM⁻/⁻IL-4Rα⁻/lox, and IL-4Rα⁻/lox mice and significantly higher (p < 0.0001) than those recorded from global IL-4Rα⁻/⁻ animals (Figure 1B). In line with the non-healing progressive disease phenotype displayed by macrophage/neutrophil IL-4Rα⁻/⁻ mice, parasite antigen induced spleen cell IFN-γ production was similar to IL-4Rα⁻/lox mice and significantly less (p < 0.01) than that of global IL-4Rα⁻/⁻ mice (Figure 1C). Antigen induced splenocyte IL-4 production was similar in all 3 strains (Figure 1D), demonstrating once again that IL-4 induction can be independent of IL-4Rα signaling [6,14–16]. Further studies demonstrated that the close similarities in the disease phenotypes of LysM⁻/⁻IL-4Rα⁻/lox and IL-4Rα⁻/lox mice were independent of site, dose of inoculum, and life cycle stage initiating infection (data not shown). These data suggest that the expression of IL-4Rα by a macrophage/neutrophil population is not important in determining susceptibility to L. mexicana infection.

### IL-4Rα signaling via CD4⁺ T cells is essential for progressive non-healing disease following infection with L. mexicana

In subsequent studies, infection of CD4⁺ T cell specific (Lck⁺⁺IL-4Rα⁻/lox) IL-4Rα⁻/⁻ mice with 5 × 10⁴ L. mexicana amastigotes into the shaven base of the tail resulted in control of the lesion growth observed in control IL-4Rα⁻/lox mice (wild-type equivalent). Interestingly, in one experiment using male mice, lesions in Lck⁺⁺IL-4Rα⁻/lox mice did not heal completely, while experiments utilizing female mice fully resolved (Figure S1). Consequently, to confirm and further investigate this apparent gender-dependent difference in control of L. mexicana infection male and female Lck⁺⁺IL-4Rα⁻/lox, control IL-4Rα⁻/lox, and global IL-4Rα⁻/⁻ mice were infected in parallel with 5 × 10⁴ L. mexicana amastigotes into the shaven base of the tail (Figure 2A–D). While infected global IL-4Rα⁻/⁻ mice displayed a non-healing growth phenotype, lesion growth was progressive in control IL-4Rα⁻/lox mice (Figure 2A and B). These disease phenotypes were independent of gender. By comparison L. mexicana infected female CD4⁺ T cell specific (Lck⁺⁺IL-4Rα⁻/lox) IL-4Rα⁻/⁻ mice developed lesions which completely healed after 4–5 weeks (Figure 2A), while male CD4⁺ T cell specific (Lck⁺⁺IL-4Rα⁻/lox) IL-4Rα⁻/⁻ developed lesions which failed to fully heal (Figure 2B). Indeed in agreement with lesion size parasite burdens up until week 6 were similar in both male Lck⁺⁺IL-4Rα⁻/lox and IL-4Rα⁻/lox mice (Figure S2).

Parasite numbers at the termination of the study at week 12 were of a similar order of magnitude in both female and male control IL-4Rα⁻/lox mice while global IL-4Rα⁻/⁻ mice of both sexes were equally able to control infection with L. mexicana (Figure 2C and D). By contrast while infected CD4⁺ T cell specific (Lck⁺⁺IL-4Rα⁻/lox) IL-4Rα⁻/⁻ mice of both sexes were able to significantly control parasite growth (p < 0.0001 and p < 0.01 respectively for female and male mice), male mice (Figure 2D) were significantly limited in this ability and had significantly higher parasite burdens (p < 0.001) than female mice (Figure 2C).

### IL-4Rα signaling via CD4⁺ T cells inhibits the production of a specific Th1 response following infection with L. mexicana

L. mexicana infection of CD4⁺ T cell specific (Lck⁺⁺IL-4Rα⁻/lox) IL-4Rα⁻/⁻ mice resulted in an enhanced Th1 response in both male and female Lck⁺⁺IL-4Rα⁻/lox mice compared with control IL-4Rα⁻/lox mice, as demonstrated by significantly enhanced antigen induced splenocyte IFN-γ production (Figure 3A and B; p < 0.025 for females; p < 0.01 for males). As previously described, antigen stimulated splenocyte IFN-γ production from infected global IL-4Rα⁻/⁻ mice was significantly higher than for wild-type equivalent (IL-4Rα⁻/lox) mice and this was true whether examining female or male mice (p < 0.02). Antigen stimulated splenocytes from infected female but not male Lck⁺⁺IL-4Rα⁻/lox mice produced significantly more IFN-γ than antigen stimulated splenocytes from infected global IL-4Rα⁻/⁻ animals. An expanded Th1 response was also indicated by enhanced antigen specific IgG2a production compared with control IL-4Rα⁻/lox mice, and in magnitude similar to that generated by global IL-4Rα⁻/⁻ mice (Figure 3C and D). However, while specific IgG2a production in the absence of IL-4Rα signaling via CD4⁺ T cells in female Lck⁺⁺IL-4Rα⁻/lox mice was significantly greater (p < 0.025) than in
infected control IL-4Rα−/−/lox mice as early as week 6 post-infection (Figure 3C) it was not until week 12 post-infection that male LckcreIL-4Rα/lox mice were producing significantly more IgG2a (p < 0.025) than their infected control IL-4Rα−/−/lox counterparts (Figure 3D). Similar results were recorded in 3 separate experiments. IL-4Rα signaling via CD4+ T cells promotes the induction of a Th2 response following infection with L. mexicana differentially in male and female mice

A clear dichotomy in antigen-induced splenocyte IL-4 production was identified between infected female and male LckcreIL-4Rα/lox mice both compared with each other and compared with their wild-type equivalent counterparts (Figure 4A and B). Splenocyte IL-4 production was barely detectable in female LckcreIL-4Rα−/−/lox mice, and significantly less than IL-4 production by male LckcreIL-4Rα−/−/lox mice (p < 0.01). On the other hand, antigen induced splenocyte IL-4 production was similar in all infected male mice, independent of IL-4Rα expression (Figure 4B). Similar results were obtained with another Th2 cytokine, IL-5 (Figure 4C and D), as well as IL-10 (Figure 4E and F), with production of both cytokines significantly lower in female but not male LckcreIL-4Rα−/−/lox compared with similarly infected sex matched control IL-4Rα−/−/lox mice. Similarly, Th2 associated antigen specific IgG1 production was significantly less in infected female (p<0.05 week 12) but not infected male LckcreIL-4Rα−/−/lox mice compared with their respective control IL-4Rα−/−/lox counterparts (Figure S2). Minimal IgG1 production was detected in the serum of infected global IL-4Rα−/−/lox mice. Total IgE levels in infected female and male LckcreIL-4Rα−/−/lox mice were similar.
to each other and intermediate between those induced in control IL-4Rα−/− and the absence of IgE in infected IL-4Rα−/− mice (Figure S3).

Anti-CD3 and ConA stimulation (Figure 5A and B) of spleen cells from 12 week infected mice demonstrated quite clearly that not only was IL-4 production from female LckcreIL-4Rα2/lox mice significantly less than that of female control IL-4Rα2/lox mice (p, 0.003 for ConA and p, 0.01 for anti-CD3 respectively), but also significantly less than similarly treated male LckcreIL-4Rα2/lox mice (p, 0.02 for ConA and p, 0.05 for anti-CD3 respectively). Conversely male LckcreIL-4Rα2/lox splenocytes produced similar quantities of IL-4 to control male IL-4Rα2/lox mice with either treatment. Examination of draining inguinal lymph node cells indicated a significantly lower (p, 0.05) percentage of IL-4 and greater (p, 0.05) percentage of IFN-γ secreting CD4+ T cells in infected female but not male LckcreIL-4Rα2/lox mice compared with control sex-matched IL-4Rα2/lox mice (Figure 6 A–D).

Discussion

We have previously demonstrated that signaling via IL-4Rα plays the major role in the non-healing response of BALB/c mice following infection with Leishmania mexicana [6] and that IL-4Rα−/− mice, unlike their wild-type counterparts that produce progressively growing non-healing lesions, display a non-lesion growth disease phenotype associated with an enhanced type-1 response. In the course of the present study using macrophage/neutrophil specific IL-4Rα−/− mice (LysMcreIL-4Rα2/lox) we failed to identify any significant role for IL-4Rα signaling via macrophages/neutrophils in the normal non-healing response of BALB/c mice infected with L. mexicana. In contrast, following early lesion growth, CD4+ T cell specific IL-4Rα−/− mice were able to inhibit disease progression. However, while lesions in female CD4+ T cell specific (LckcreIL-4Rα2/lox) IL-4Rα−/− mice healed those in male CD4+ T cell specific (LckcreIL-4Rα2/lox) IL-4Rα−/− mice...
IL-4Rx·CD4⁺ T Cells Promote Leishmania mexicana

Females

Males

Figure 3. IL-4Rx deficiency in CD4⁺ T cells results in enhanced Th1 responses after L. mexicana infection. L. mexicana antigen induced (10 μg/ml) splenocyte IFN-γ (Figure 3A and B), and 6 and 12 week serum IgG2a levels (Figure 3C and 3D) produced from female (Figure 3A and C) and male (Figure 3B and D) IL-4Rx intact (IL-4Rx⁺/loxp), CD4⁺ T cell specific (Lck⁺/IL-4Rx⁺/loxp) IL-4Rx⁺/loxp, and global IL-4Rx⁻/⁻ mice infected subcutaneously with 5×10⁶ amastigotes of L. mexicana. *p<0.05, **p<0.01 compared with IL-4Rx intact mice. Representative of 4 separate experiments.

IL-4Rx⁺·CD4⁺ T Cells Promote L. mexicana infection. L. mexicana antigen induced (10 μg/ml) splenocyte IFN-γ (Figure 3A and B), and 6 and 12 week serum IgG2a levels (Figure 3C and 3D) produced from female (Figure 3A and C) and male (Figure 3B and D) IL-4Rx intact (IL-4Rx⁺/loxp), CD4⁺ T cell specific (Lck⁺/IL-4Rx⁺/loxp) IL-4Rx⁺/loxp, and global IL-4Rx⁻/⁻ mice infected subcutaneously with 5×10⁶ amastigotes of L. mexicana. *p<0.05, **p<0.01 compared with IL-4Rx intact mice. Representative of 4 separate experiments.

doi:10.1371/journal.pntd.0000930.g003

Persisted. Furthermore, although both female and male CD4⁺ T cell specific (Lck⁺/IL-4Rx⁺/loxp) IL-4Rx⁻/⁻ mice had significantly enhanced type-1 responses compared with IL-4Rx intact (IL-4Rx⁺/loxp) mice, male CD4⁺ T cell specific (Lck⁺/IL-4Rx⁺/loxp) IL-4Rx⁻/⁻ mice maintained strong type-2 responses compared with their female counterparts.

Although signaling via IL-4Rx plays a significant role in the outcome of infection with L. mexicana as well as L. major [6,8–9,15] the cell targets for IL-4/IL-13 activity and whether they promote or inhibit the disease process differ significantly between species. Thus, while IL-4Rx signaling via macrophages/neutrophils promotes early lesion growth in L. major infected BALB/c mice and macrophage/neutrophil specific (LysM⁺/IL-4Rx⁻/loxp) IL-4Rx⁻/⁻ mice display delayed lesion growth [8], we have failed to identify any contributory role for IL-4Rx signaling via macrophages/neutrophils during L. mexicana infection. The control of L. major early in infection in LysM⁺/IL-4Rx⁻/loxp mice has been identified as being due to enhanced macrophage microbicidal NO mediated activity in the absence of alternative macrophage activation. What may be critical in this regard is that L. amazonensis parasites, which belong to the “mexicana” complex of parasites, have been shown to be more resistant to macrophage-mediated control than L. major requiring higher levels of NO to induce killing [16–17]. Furthermore, recent evidence indicates that, unlike L. major, there is in fact enhanced replication of the amastigote stage of L. amazonensis in IFN-γ-stimulated murine macrophages [18], reportedly due to the induction of a novel L-arginine pathway independent of iNOS or host arginase [19]. In addition it has been demonstrated that arginase null-mutant L. mexicana have attenuated virulence in vitro and in vivo with the indication that the parasite arginase has a potential role in depleting host L-arginine available for iNOS activity [20–21]. Furthermore, the authors suggest that there could be different roles of arginase between L. mexicana and L. major as the Th2 response is blunted in animals
infected with arginase null mutant *L. mexicana* parasites while pharmacological inhibition of arginase during *L. major* infection did not inhibit the Th2 immune response [22].

CD4+ T cell specific (LckcreIL-4Rα2/lox) IL-4Rα2/− mice are more resistant than global IL-4Rα2/− mice to infection with *L. major*, indicating that in the absence of a polarized Th2 response, there is a role for an IL-4/IL-13 responsive non-CD4+ T cell in early resistance to infection [9]. Conversely CD4+ T cell specific (LckcreIL-4Rα2/lox) IL-4Rα2/− mice are more susceptible than global IL-4Rα2/− mice to infection with *L. mexicana*, indicating a role for an IL-4/IL-13 responsive non CD4+ T cell population in early susceptibility. We have now studied the course of *L. mexicana* infection in newly generated iLckcreIL-4Rα2/lox female and male mice that have IL-4Rα deleted on all T cell populations [23]. These produce the same disease and immunological phenotypes as CD4+ T cell specific (LckcreIL-4Rα2/lox) IL-4Rα2/− mice (data not shown). Consequently IL-4 responsive CD8+ T cells do not play a role in early susceptibility or the non-healing response following infection with *L. mexicana*. Studies utilizing macrophage specific BALB/c IL-4Rα2/− mice have demonstrated that IL-4/IL-13 operates through this population to enhance *L. major* parasite growth via alternative macrophage activation [8] and consequently these are unlikely to be the population driving a Th1 response in CD4+ T cell specific (LckcreIL-4Rα2/lox) IL-4Rα2/− mice. However, IL-4 treatment of BALB/c mice prior to T cell priming has previously been demonstrated to instruct dendritic cells to produce IL-12 and facilitate a protective Th1 response against *L. major* [24] and is required for protective type-1 responses to *Candida* [25]. In addition IL-13 is able to prime monocytes for IL-12 production[26], which is also observed in listeriosis [27].

![Figure 4. IL-4Rα deficiency in CD4+ T cells results in decreased specific Th2 responses in female mice. *L. mexicana* antigen induced (10 μg/ml) splenocyte IL-4 (Figure 4A and B), IL-5 (Figure 4C and D) and IL-10 (Figure 4E and F) produced from female (Figure 4A, C and E) and male (Figure 4B, D and F) IL-4R α intact (IL-4Rα−/lox), CD4+ T cell specific (LckcreIL-4Rα−/lox) IL-4Rα−/−, and global IL-4Rα−/− mice infected sub-cutaneously with 5 x 10⁶ amastigotes of *L. mexicana*. *p<0.05, **p<0.01 compared with IL-4Rα intact mice. Representative of 4 separate experiments. doi:10.1371/journal.pntd.0000930.g004](http://www.plosntds.org/7 January 2011 | Volume 5 | Issue 1 | e930)
Furthermore both IL-4 and IL-13 promote CD40L-induced IL-12 production by macrophages and dendritic cells [28]. This would indicate that dendritic cells may be the IL-4/IL-13 responsive cells facilitating protection against L. major in the absence of IL-4Rα responsive CD4+ T cells in BALB/c mice. As no distinct disease phenotype could be discerned in macrophage/neutrophil specific (LyM<sup>cre</sup>IL-4Rα<sup>+/lox</sup>) IL-4Rα<sup>−/−</sup> mice compared with IL-4Rα intact animals infected with L. mexicana, no IL-4/IL13 responsive non-T cell population can easily be ruled out in promoting early infection against this parasite. While a role for B cells and antibody production in the non-healing response to infection against this parasite. While a role for B cells and antibody production in the non-healing response to infection against this parasite. While a role for B cells and antibody production in the non-healing response to infection against this parasite. While a role for B cells and antibody production in the non-healing response to infection against this parasite.

Unlike the epidemiological and experimental reports on L. major and L. tropica which identify females as more susceptible, females are more resistant than males to cutaneous infection with L. mexicana [5,12,31–33] and visceral leishmaniasis caused by L. donovani (humans) [34–35] or L. infantum (dogs) [36]. Female DBA/2 mice infected with L. mexicana develop much stronger Th1 responses, as measured by IFN-γ production, delayed-type hypersensitivity and IgG2a antibody levels, than similarly infected male mice [12,32]. Similarly, in humans infected with L. mexicana, females generally have increased Th1 responses as measured by DTH reactions and decreased Th2 responses as measured by IgE production than males [33]. The present studies using CD4+ T cell specific IL-4Rα<sup>−/−</sup> BALB/c mice have revealed a previously undetected, underlying male susceptibility to L. mexicana involving T cells. Thus, unlike female mice, male mice were unable to resolve infection and overall had a less polarized Th1 response and more polarized Th2 than their female counterparts. This was associated with IL-4 production independently of IL-4Rα signaling in male but not female CD4+ T cell specific Lck<sup>cre</sup>IL-4Rα<sup>−/lox</sup> IL-4Rα<sup>−/−</sup> BALB/c mice. The L. mexicana induced IL-4 producing Th2 phenotype in male Lck<sup>cre</sup>IL-4Rα<sup>−/lox</sup> BALB/c mice was not the result of differential Cre-mediated deletion efficiency of IL-4Rα in male mice as compared with female mice, as no CD4+ T cell population expressing IL-4Rα was detected from either gender (data not shown). While IL-4 production independently of IL-4Rα signaling has been observed in a number of immunological models previously [6,14–15] this is the first time a sex associated influence on this ability has been identified. How significant this could be with regard to the numerous gender related differences observed in inflammatory and infectious diseases is an intriguing question but outside the scope of the present study.

To conclude in this study utilising tissue specific IL-4Rα<sup>−/−</sup> mice we demonstrate that upon infection with L. mexicana initial lesion growth is dependent on a non-CD4+ T cell population responsive to IL-4/IL-13, while progressive infection is dependent on CD4+ T cells responsive to IL-4. Furthermore whether lesions heal or not is gender determined, suggesting a subtle but
significant effect of sex hormones on CD4+ T cell function whereby infected male but not female CD4+ T cell specific IL-4Rα−/− mice can drive IL-4 production independently of IL-4Rα signaling.

Supporting Information

Figure S1  Female but not male T cell specific IL-4Rα−/− mice heal following L. mexicana infection. Mean lesion growth (Figure 1A and B) in female (Figure 1A) and male (Figure 1B) IL-4Rα intact (IL-4Rα−/+), CD4+ T cell specific (LckcreIL-4Rα−/−) IL-4Rα−/−, and global IL-4Rα−/− mice infected sub-cutaneously with 5×10^6 amastigotes of L. mexicana. These are the results from 2 separate experiments carried out at different times the first using females (Figure 1A), the second using males (Figure 1B). While lesions healed in female CD4+ T cell specific (LckcreIL-4Rα−/−) IL-4Rα−/− mice they persisted in male CD4+ T cell specific (LckcreIL-4Rα−/−) IL-4Rα−/−. Results are mean±s.e. Additional experiments utilised male and female groups infected in parallel.
