Aeromonas caviae is a Gram-negative, motile and rod-shaped facultative anaerobe that is increasingly being recognized as a cause of diarrhea in children. Here we present the first genome sequence of an Aeromonas strain that was isolated as the sole pathogen from a child with profuse diarrhea.

Aeromonads are Gram-negative organisms belonging to the Gammaproteobacteria. Nineteen species of Aeromonas can be distinguished by biochemical and molecular techniques (5); most do not have a strong association with disease. However, Aeromonas salmonicida is a well-established fish pathogen, and Aeromonas caviae, Aeromonas hydrophila, and Aeromonas veronii account for 85% of isolates derived from human infections (5). While Aeromonas sp. can be isolated from ca. 2% of healthy individuals, association with stools from patients with diarrhea has been reported to be as high as 10.8% (4, 5). Here we report the genome sequence of Aeromonas caviae Ae398. This strain was isolated from a 17-month-old male at the Hospital Universitário Pedro Ernesto, Rio de Janeiro, Brazil. The patient presented with gastroenteritis and diarrhea, without mucus or blood, approximately three times a day for 3 weeks. Aeromonas caviae Ae398 was isolated as the sole pathogen from a stool specimen collected 3 weeks after onset of symptoms and was identified by conventional biochemical tests (3). The isolate presented extracellular enzymatic activities, resistance to several antibiotics, and adherence to epithelial cell monolayers (2, 3, 7, 9, 10).

Whole-genome shotgun sequencing of Aeromonas caviae Ae398 was performed by a combination of 454 GS-FLX (162,066 shotgun reads of average length 358 bp) and Illumina sequencing (25,272,910 51-bp paired-end reads), leading to a final assembly of 149 contigs (25,272,910 51-bp paired-end reads), leading to a final assembly of 149 contigs >200 bp. The assembly represented 200 bp. The assembly represented 4,339,218 bp, with a mean contig size of 29,793 bp, an N50 value of 76,364 bp (where N50 is the contig length such that at least 50% of the bases of the assembly are contained within contigs of this size or greater), and an average G+C content of 61.4%. Nucmer pairwise genome alignments (6) show the Aeromonas caviae Ae398 genome displays the highest overall synteny with Aeromonas hydrophila ATCC 7966 (70.4% aligned) and Aeromonas salmonicida A449 (61.7% aligned) and average nucleotide identities of 88.8% and 86.8% across aligned regions, respectively.

The deduced size of the Aeromonas caviae Ae398 genome (4.43 Mb) is similar to those of Aeromonas hydrophila ATCC 7966 (4.47 Mb) and Aeromonas salmonicida A449 (4.70 Mb). Aeromonas caviae Ae398 harbors at least one conjugative plasmid of >30 kb, although it remains in several contigs in the assembly. Five different insertion (IS) element types are present in Aeromonas caviae Ae398, whereas Aeromonas salmonicida possesses 88 copies of 10 different IS elements and Aeromonas hydrophila completely lacks IS elements (8, 11). An ~33-kb putative prophage bounded by 55-bp repeats is found at the tRNA-Leu attachment site in Aeromonas caviae Ae398; the 3′ region shares high identity with phiO18P (1), whereas the 5′ region is most similar to structural genes from non-Aeromonas phage genomes.

Aeromonas caviae contains many putative virulence genes, including those encoding a type 2 secretion system (11), an RTX toxin, and polar flagella. The genome sequence of Aeromonas caviae Ae398 is an important milestone in understanding the diversity and pathogenesis of Aeromonas caviae, opening new avenues for investigating the pathogenic processes of this organism and allowing robust diagnostics to be developed.

Nucleotide sequence accession numbers. The assembly was deposited at the WGS division of DDBJ/EMBL/GenBank under accession no. CACP01000001 to CACP01000149.
