IMPROVED BOUNDS FOR THE KAKEYA MAXIMAL CONJECTURE IN HIGHER DIMENSIONS

JONATHAN HICKMAN, KEITH M. ROGERS, AND RUIXIANG ZHANG

Abstract. We adapt Guth’s polynomial partitioning argument for the Fourier restriction problem to the context of the Kakeya problem. By writing out the induction argument as a recursive algorithm, additional multiscale geometric information is made available. To take advantage of this, we prove that direction-separated tubes satisfy a multiscale version of the polynomial Wolff axioms. Altogether, this yields improved bounds for the Kakeya maximal conjecture in $\mathbb{R}^n$ with $n = 5$ or $n \geq 7$ and improved bounds for the Kakeya set conjecture for an infinite sequence of dimensions.

1. Introduction

For $n \geq 2$ and small $\delta > 0$, a $\delta$-tube is a cylinder $T \subset \mathbb{R}^n$ of unit height and radius $\delta$, with arbitrary position and arbitrary orientation $\text{dir}(T) \in S^{n-1}$. A family $\mathcal{T}$ of $\delta$-tubes is direction-separated if $\{\text{dir}(T) : T \in \mathcal{T}\}$ forms a $\delta$-separated subset of the unit sphere.

Conjecture 1.1 (Kakeya maximal conjecture). Let $p \geq \frac{n}{n-1}$. For all $\varepsilon > 0$, there exists a constant $C_{\varepsilon,n} > 0$ such that

$$\left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{L^p(\mathbb{R}^n)} \leq C_{\varepsilon,n} \delta^{(n-1-n/p) - \varepsilon \left( \sum_{T \in \mathcal{T}} |T| \right)^{1/p}} \quad (K_p)$$

whenever $0 < \delta < 1$ and $\mathcal{T}$ is a direction-separated family of $\delta$-tubes.

By an application of Hölder’s inequality, one may readily verify that if $(K_p)$ holds for $p = \frac{n}{n-1}$, then, for all $\varepsilon > 0$, there exists a constant $c_{\varepsilon,n} > 0$ such that

$$\left| \bigcup_{T \in \mathcal{T}} T \right| \geq c_{\varepsilon,n} \delta^{\varepsilon} \sum_{T \in \mathcal{T}} |T|.$$

This can be interpreted as the statement that any direction-separated family of $\delta$-tubes is ‘essentially disjoint’. A more refined argument shows that if $(K_p)$ holds for a given $p$, then every Kakeya set in $\mathbb{R}^n$ (that is, every compact set that contains a unit line segment in every direction) has Hausdorff dimension at least $p'$, the conjugate exponent of $p$. Thus, Conjecture 1.1 would imply the Kakeya set conjecture, that Kakeya sets in $\mathbb{R}^n$ have Hausdorff dimension $n$; see, for instance, [5, 22, 28].

For $n = 2$, the set conjecture was proven by Davies [12] and the maximal conjecture was proven by Córdoba [11] in the seventies. Both conjectures remain challenging and important open problems in higher dimensions; for partial results, see [13, 19, 10, 5, 11, 34, 39, 6, 26, 24, 31, 37, 4, 13, 16, 17] and references therein.

Figure 1. The state-of-the-art for the Kakeya maximal conjecture in low dimensions. New results are highlighted.

In 1999, Bourgain [6] improved the state-of-the-art in higher dimensions using sum-difference theory from additive combinatorics. This technique was refined by Katz and Tao [26, 27, 28], proving that Conjecture 1.1 is true in the range \( p \geq 1 + \frac{7}{n+1} \). The purpose of the present article is to extend this range using a different approach.

**Theorem 1.2.** Conjecture 1.1 is true in the range

\[
p \geq 1 + \min_{2 \leq k \leq n} \max \left\{ \frac{2n}{(n-1)n+(k-1)k}, \frac{1}{n-k+1} \right\}.
\]

When \( k = n \), the first entry of the maximum of (1) takes the conjectured value; however, the second entry only reaches this value at the other extreme, when \( k = 2 \). A reasonable compromise can be found by taking \( k \) to be the closest integer to \( (\sqrt{2} - 1)n + 1 \), at which point we find, for instance, that the Kakeya maximal conjecture holds in the range

\[
p \geq 1 + \frac{1}{2-\sqrt{2}} \frac{1}{n-1},
\]

which is an improvement over the Katz–Tao maximal bound [27]. See Figure 1 for the state-of-the-art in low dimensions. Theorem 1.2 also implies improved bounds for the Kakeya set conjecture in certain dimensions. Further discussion of the numerology is contained in the final section of the article.

The proof of Theorem 1.2 is based on the polynomial method, which was introduced in the context of the Kakeya problem by Dvir in his celebrated proof [14] of Wolff’s finite field Kakeya conjecture [42]. The polynomial method has been adapted to analyse Kakeya sets in Euclidean space in, for instance, works of Guth [16, 17] and Guth and Zahl [22]. A key tool here is polynomial partitioning, introduced by Guth and Katz in their resolution of the two dimensional Erdős distance conjecture [21]. Of most relevance to the present article is the recent work of Guth [18, 19] which adapted the partitioning technique to the context of the Fourier restriction problem.

In [18, 19, 22], polynomial partitioning was used to study collections of direction-separated tubes. This led to the consideration of configurations of tubes that are

\footnote{In all dimensions the range (1) is in fact strictly larger than (2); the latter is included to provide a ready comparison with the maximal bounds from [27].}
partially contained in the neighbourhood of a real algebraic variety. Guth proved
the following cardinality estimate for direction-separated tubes in three dimensions
\[ 18, \text{Lemma 4.9} \] and conjectured that it should hold in higher dimensions \[ 19, \text{Conjecture B.1} \]. This was confirmed by Zahl \[ 44 \] in four dimensions and then in
general by Katz and the second author \[ 25 \].

**Theorem 1.3** (\[ 18, 44, 25 \]). For all \( n \geq k \geq 1, d \geq 1 \) and \( \varepsilon > 0 \), there is a
constant \( C_{n,d,\varepsilon} > 0 \) such that
\[
\# \left\{ T \in \mathbb{T} : |T \cap B_{\lambda_k} \cap N_{\rho}Z_k| \geq \lambda_k|T| \right\} \leq C_{n,d,\varepsilon} \left( \frac{\rho}{\lambda_k} \right)^{n-k} \delta^{-(n-1)-\varepsilon}
\]
whenever \( 0 < \delta \leq \rho \leq \lambda_k \leq 1 \), \( T \) is a direction-separated family of \( \delta \)-tubes and
\( Z_k \subset \mathbb{R}^n \) is a \( k \)-dimensional algebraic variety of degree \( \leq d \).

Here \( N_rE \) denotes the \( r \)-neighbourhood of \( E \) for any \( r > 0 \) and \( E \subset \mathbb{R}^n \) and \( B_r \) is a choice of ball in \( \mathbb{R}^n \) of radius \( r \). The relevant algebraic definitions are recalled
in Section 3.1 below. In the language of \[ 19 \], this theorem states that direction-
separated tubes satisfy the polynomial Wolff axioms; this terminology is recalled
and discussed in further detail in the final section of the paper.

After adapting Guth’s restriction argument \[ 18, 19 \] to the context of the Kakeya
maximal problem, one finds that Theorem 1.3 can be used to obtain improved
bounds in certain intermediate dimensions: see the final section for more details.
However, by rewriting Guth’s induction argument as a recursive algorithm, one is
readily able to take advantage of the following strengthened version of Theo-
rem 1.3.

**Theorem 1.4.** For all \( n \geq m \geq k \geq 1, d \geq 1 \) and \( \varepsilon > 0 \), there is a constant
\( C_{n,d,\varepsilon} > 0 \) such that
\[
\# \bigcap_{j=k}^{m} \left\{ T \in \mathbb{T} : |T \cap B_{\lambda_j} \cap N_{\rho}Z_j| \geq \lambda_j|T| \right\} \leq C_{n,d,\varepsilon} \left( \prod_{j=k}^{m} \frac{\rho}{\lambda_j} \right)^{n-m} \delta^{-(n-1)-\varepsilon}
\]
whenever \( 0 < \delta \leq \rho \leq \lambda_k \leq \ldots \leq \lambda_m \leq 1 \), \( T \) is a direction-separated family of
\( \delta \)-tubes, \( Z_j \subset \mathbb{R}^n \) are \( j \)-dimensional algebraic varieties of degree \( \leq d \) and the balls
\( B_{\lambda_j} \) are nested: \( B_{\lambda_k} \subseteq \ldots \subseteq B_{\lambda_m} \subset \mathbb{R}^n \).

Taking the varieties \( Z_j \) to be nested \( j \)-planes reveals that the cardinality estimate
of Theorem 1.4 is sharp up to the factor of \( C_{n,d,\varepsilon} \delta^{-\varepsilon} \). The proof will follow the
argument of \[ 25 \] once a relevant Wongkew-type volume bound (in the spirit of
\[ 43 \]) has been established. The mixture of trigonometric and algebraic arguments
involved in the proof of this volume bound constitutes the most novel part of the
article.

**Remark 1.5.** In a late stage of the development of this project, the authors dis-
covered that J. Zahl has proved the same maximal results as Theorem 1.2 using similar
methods. In particular, J. Zahl has independently established Theorem 1.4 and,
moreover, was able to use this result to prove a strengthened version of Theorem 4.1
involving \( k \)-linear (as opposed to \( k \)-broad) estimates.

The remainder of the article is organised as follows:

- In Section 2 some notational conventions are fixed.
• In Section 3 the proof of Theorem 1.4 is presented after first establishing the relevant Wongkew-type volume bound.
• In Section 4 the proof of Theorem 1.2 is reduced to estimating the so-called $k$-broad norms for the Kakeya maximal function, paralleling work on oscillatory integrals from [7, 18, 19].
• In Section 5 basic properties of $k$-broad norms are reviewed.
• In Section 6 the polynomial partitioning theorem from [19] is recalled and applied to the $k$-broad norms.
• In Section 7 the recursive algorithm is described, culminating in a structural statement of algebraic nature for the Kakeya maximal problem.
• In Section 8 the structural statement is combined with Theorem 1.4 to conclude the proof of Theorem 1.2.
• In Section 9 the applications to the Kakeya set conjecture and other related problems are discussed.
• Appended is a review of some facts from real algebraic geometry used in Section 3.

Acknowledgement. The first author thanks both Larry Guth and Joe Karmazyn for helpful discussions during the development of this project.

2. Notational conventions

We call an $n$-dimensional ball $B_r$ of radius $r$ an $r$-ball. The intersection of $S^{n-1}$ with a ball is called a cap. The $\delta$-neighbourhood of a set $E$ will be denoted by $N_\delta E$.

The arguments will involve the admissible parameters $n, p$ and $\varepsilon$ and the constants in the estimates will be allowed to depend on these quantities. Moreover, any constant is said to be admissible if it depends only on the admissible parameters. Given positive numbers $A, B \geq 0$ and a list of objects $L$, the notation $A \lesssim_L B$, $B \gtrsim_L A$ or $A = O_L(B)$ signifies that $A \leq C_L B$ where $C_L$ is a constant which depends only on the objects in the list and the admissible parameters. We write $A \sim_L B$ when both $A \lesssim_L B$ and $B \gtrsim_L A$.

The cardinality of a finite set $A$ is denoted by $\#A$. A set $A'$ is said to be a refinement of $A$ if $A' \subseteq A$ and $\#A' \gtrsim \#A$. In many cases it will be convenient to pass to a refinement of a set $A$, by which we mean that the original set $A$ is replaced with some refinement.

3. Multiscale polynomial Wolff axioms: Proof of Theorem 1.4

In this section we prove Theorem 1.4. A minor modification of the argument used to prove Theorem 1.3 in [25] reduces matters to establishing a “Wongkew-type lemma”. The details of this reduction are described in Section 3.3 below. In the simplest case where $k = m$ (which corresponds to Theorem 1.3), after the reduction all that is needed is Wongkew’s original lemma [43], which is used to bound the volume of the semialgebraic set $Z_k \cap B_{\lambda_k}$. In the general case the problem is to obtain bounds for the volume of other semialgebraic sets $S_m(I_m, \rho)$ which do not fall directly under the scope of [43]. These sets arise from the multiscale hypotheses and are defined in Section 3.2.

3.1. Algebraic definitions. Before continuing, it is perhaps useful to clarify some of the terminology featured in the statement of Theorem 1.4 and also in the proof.
Definition 3.1. A set \( Z \subseteq \mathbb{R}^n \) will be referred to as a variety if it can be expressed as \( Z = Z(P_1, \ldots, P_r) \) for a collection of polynomials \( P_i : \mathbb{R}^n \to \mathbb{R} \) for \( 1 \leq i \leq r \) where

\[
Z(P_1, \ldots, P_r) := \{ x \in \mathbb{R}^n : P_1(x) = \cdots = P_r(x) = 0 \}. \tag{3}
\]

For the case of interest (namely, where \( Z \) is a transverse complete intersection: see Definition 5.1 below), \( Z \) will always be a real smooth submanifold of \( \mathbb{R}^n \). Here the dimension \( \dim Z \) is defined to be the dimension of \( Z \) as a real smooth manifold. The results of this section hold for more general varieties which potentially admit singular points, with a suitably generalised definition of dimension, although we will not discuss the details of this definition here (see, for instance, [1]).

Definition 3.2. Given a variety \( Z \) the degree of \( Z \) is

\[
\deg Z := \inf \sum_{j=1}^r \deg P_j, \tag{4}
\]

where the infimum is taken over all possible representations of \( Z \) of the form (3).

The proof of Theorem 1.4 will involve the analysis of a more general class of sets.

Definition 3.3. A set \( S \subseteq \mathbb{R}^n \) is semialgebraic if there exists a finite collection of polynomials \( P_{i,j}, Q_{i,j} : \mathbb{R}^n \to \mathbb{R} \) for \( 1 \leq i \leq r, 1 \leq j \leq s \) such that

\[
S = \bigcup_{i=1}^r \{ x \in \mathbb{R}^n : P_{i,1}(x) = \cdots = P_{i,s}(x) = 0, Q_{i,1}(x) > 0, \ldots, Q_{i,s}(x) > 0 \}. \tag{4}
\]

Definition 3.4. Given a semialgebraic set \( S \subseteq \mathbb{R}^n \) the complexity of \( S \) is

\[
\inf \left( \sum_{i,j} \deg P_{i,j} + \deg Q_{i,j} \right)
\]

where the infimum is taken over all possible representations of \( S \) of the form (4).

A number of fundamental results in the theory of semialgebraic sets will be used in the proof of Theorem 1.4 including the Tarski–Seidenberg projection theorem and Gromov’s algebraic lemma. For the reader’s convenience, the relevant statements are recorded in the appendix.

3.2. A Wongkew-type lemma. The main new ingredient in the proof of Theorem 1.4 will be a bound for the Lebesgue measure of certain semialgebraic sets \( S_m(I_m, \rho) \) given by unions of line segments. Before defining these sets some basic reductions are made and some useful notion is introduced.

We choose our coordinates in such a way that the \( \lambda_m \)-ball \( B_{\lambda_m} \) is centred at the origin and a reasonably large proportion of our direction-separated \( \delta \)-tubes have core lines which can be parametrised by

\[
l_{a,d}(t) := (a, 0) + t(d, 1), \quad t \in \mathbb{R},
\]

for some \( a, d \in [-1, 1]^{n-1} \). Then, for each \( j = k, \ldots, m \), we partition the orthogonal projection of \( B_{\lambda_j} \) onto the \( t \)-axis into \( 4nd \) disjoint intervals \( I_j \subset [\lambda_j, 1] \) of length \( \lambda_j/(2nd) \), where \( d \) bounds the degree of our varieties \( Z_k, \ldots, Z_m \).

\[\text{Note that here, in contrast with much of the algebraic geometry literature, the ideal generated by the } P_i \text{ is not required to be irreducible.}\]
Given any interval $J \subseteq \mathbb{R}$, we define

$$S_m(J, \rho) := \bigcap_{j=k}^m \{ l_{a,d}(t) : t \in J, (a,d) \in [-1,1]^{2(n-1)}, l_{a,d}(I_j) \subseteq N_{\rho}Z_j \cap B_{\lambda_j} \};$$

see Figure 2 for a diagrammatic description of this set. The key problem will be to estimate the measure of these sets. Note that the measure of $S_m(I_m, \rho)$ depends on the specific choice of $I_k, \ldots, I_m$; however, our bounds will be uniform over any choice and so we suppress this dependence in the notation. An example of such a bound follows from the $m$-dimensional version of Wongkew's theorem [43] (see Theorem A.1 in the appendix), which immediately implies that

$$|S_m(I_m, \rho)| \lesssim d \rho^{-m}.$$  \hspace{1cm} (5)

This estimate only uses the $m$-dimensional information, and our first task is to improve this bound using the additional lower dimensional information.

In order to improve (5), we will consider both $S_{\ell}(I_{\ell+1}, \rho)$ and $S_{\ell}(I_{\ell+1}, 2\rho)$, the latter of which need not be contained in either $N_{\rho}Z_{\ell} \cap B_{\lambda_{\ell}}$ or $N_{\rho}Z_{\ell+1} \cap B_{\lambda_{\ell+1}}$. Roughly speaking, there are two steps to the argument:

**Step 1:** We bound $|S_{\ell+1}(I_{\ell+1}, \rho)|$ in terms of $|S_{\ell}(I_{\ell+1}, 2\rho)|$ using trigonometry and Wongkew’s theorem [43].

**Step 2:** We bound $|S_{\ell}(I_{\ell+1}, 2\rho)|$ in terms of $|S_{\ell}(I_{\ell}, 4\rho)|$ using an algebraic argument that borrows ideas from [25].

Iterating these steps yields a bound for $|S_m(I_m, \rho)|$ in terms of $|S_k(I_k, 4^{m-k}\rho)|$; at which point we can use the $k$-dimensional version of Wongkew’s theorem rather than the $m$-dimensional version. The resulting bound is presented in the following lemma.

**Lemma 3.5.** For all $n \geq m \geq k \geq 1$, $d \geq 1$ and $\varepsilon > 0$,

$$|S_m(I_m, \rho)| \lesssim d \rho^{-\varepsilon} \left( \prod_{j=k}^{m-1} \frac{\rho}{\lambda_j} \right) \lambda_m \rho^{n-m}$$
whenever $0 < \rho/4 \leq \lambda_k \leq \ldots \leq \lambda_m \leq 1$, the $j$-dimensional varieties $\mathbf{Z}_j \subset \mathbb{R}^n$ have degree $\leq d$ and $B_{\lambda_k} \subset \ldots \subset B_{\lambda_m} \subset \mathbb{R}^n$.

Taking the $j$-dimensional varieties $\mathbf{Z}_j$ to be nested $j$-planes reveals that the estimate is sharp up to the factor of $C_{n,d,\varepsilon} \rho^{-\varepsilon}$.

**Proof (of Lemma 3.5).** The proof is somewhat involved and is broken into stages.

**Initial reductions.** We may assume without loss of generality that

$$\rho \leq 4^{k-m+1} \lambda_k.$$  \hspace{1cm} (6)

Indeed, otherwise there exists a largest $k'$ such that $k + 1 \leq k' \leq m + 1$ and $\rho > 4^{k-m+1} \lambda_j$ for all $k \leq j \leq k' - 1$. If $k' = m + 1$, then the result is trivial. If $k' < m + 1$, then we may drop the $j$th condition in $S_m(I_m, \rho)$ for $k \leq j \leq k' - 1$. Relabelling $k'$ as $k$, (6) now holds.

It will also be useful to assume that the intervals $I_j$ have lengths given by some dyadic number: that is,

$$\frac{\lambda_j}{2nd} \in 2^\mathbb{Z}.$$  \hspace{1cm} (7)

This is possible by slightly enlarging the set by appropriately rounding up the $\lambda_j$'s.

**Setting up the induction.** For all $k \leq \ell \leq m$ we will prove that

$$|S_\ell(I_\ell, \rho)| \lesssim_d \rho^{-\varepsilon} \left( \prod_{j=k}^{\ell-1} \frac{\rho}{\lambda_j} \right) \lambda_\ell \rho^{n-\ell}$$  \hspace{1cm} (8)

whenever $\rho \leq 4^{k-\ell+1} \lambda_k$ and the $\lambda_j$ satisfy (7). To do this, we induct on $\ell$. For technical reasons, it will be useful to slightly enlarge the sets by redefining

$$S_\ell(J, \rho) := \bigcap_{j=k}^{\ell} \left\{ l_{a,d}(t) : t \in J, (a, d) \in Q^{2(n-1)}(\rho), l_{a,d}(I_j) \subseteq N_0 \mathbf{Z}_j \cap B_{\lambda_j + \rho} \right\}$$

where $Q^{2(n-1)}(\rho) := [-1 - \rho, 1 + \rho]^{2(n-1)}$. Clearly, any bound of the form (8) for these enlarged sets implies the same bound holds for the original $S_\ell(I_\ell, \rho)$.

By the $k$-dimensional version of Wongkew’s theorem [43] (see Theorem A.1),

$$|S_k(I_k, \rho)| \lesssim_d \lambda_k^{k-n-k}$$

whenever $\rho \leq 4 \lambda_k$ and this serves as the base case for the induction argument.

Assuming (8) holds for some $k \leq \ell \leq m - 1$, it suffices to prove that

$$|S_{\ell+1}(I_{\ell+1}, \rho)| \lesssim_d \rho^{-\varepsilon} \left( \frac{\lambda_{\ell+1}}{\lambda_k} \right)^{\ell+1} |S_\ell(I_\ell, 4\rho)|$$

whenever $\rho \leq 4^{k-\ell} \lambda_k$ and $\lambda_j/(2nd) \in 2^\mathbb{Z}$. We may also assume the non-degeneracy hypothesis that

$$|S_{\ell+1}(I_{\ell+1}, \rho)| \geq \frac{8}{\lambda_{\ell+1}^{\ell+1} \rho^{n-\ell-1}} \geq 8 \lambda_{\ell+1} \rho^{n-1},$$  \hspace{1cm} (9)

as otherwise the induction step would have closed already.
Dyadic decomposition. Recall from our initial reductions that the $I_j$ are dyadic intervals. To prove the induction step we partition $I_{\ell+1}$ into the part close to $I_\ell$, 

$$\{ t \in I_{\ell+1} : \text{dist}(t, I_\ell) \leq |I_\ell| \},$$

(10)

and dyadic parts further from $I_\ell$, 

$$\{ t \in I_{\ell+1} : 2^i|I_\ell| \leq \text{dist}(t, I_\ell) \leq 2^{i+1}|I_\ell| \}, \quad i \geq 0.$$ 

(11)

Let $J$ denote the collection of all maximal dyadic subintervals of the sets in (10) or (11). We have $S_{\ell+1}(I_{\ell+1}, \rho) = \bigcup_{J \in J} S_{\ell+1}(J, \rho) \subset \bigcup_{J \in J} S_\ell(J, \rho) \cap N_\rho Z_{\ell+1}$, where the final inclusion follows directly from the definitions. Since the $J \in J$ are contained in $I_{\ell+1}$ and are pairwise disjoint, 

$$|S_{\ell+1}(I_{\ell+1}, \rho)| \leq 4 \lambda_{\ell+1} \rho^{n-1} + \sum_{J \in J} |S_\ell(J, \rho) \cap N_\rho Z_{\ell+1}|.$$ 

By (9), the first term on the right-hand side of the above display is at most half the term on the left-hand side. Thus, it suffices to estimate the right-hand sum. Given that the balls are nested, $B_{\lambda_k} \subset \ldots \subset B_{\lambda_m} \subset \mathbb{R}^n$, we have

$$\maxdist(I_\ell, J) := \sup \{ |t - t'| : t \in I_\ell, t' \in J \} \lesssim \lambda_{\ell+1},$$

so there are no more than $2 \log(\lambda_{\ell+1}/|I_\ell|) \lesssim d \log(\rho^{-1})$ intervals $J \in J$. Thus, it will suffice to prove that

$$|S_\ell(J, \rho) \cap N_\rho Z_{\ell+1}| \lesssim_d \rho^{-\varepsilon} \left( \frac{|J|}{|I_\ell|} \right)^{\ell+1} |S_\ell(I_\ell, 4\rho)|,$$

(12)

whenever $J \in J$ satisfies $|S_\ell(J, \rho)| \geq 4|J|\rho^{n-1}$.

Inductive step: the first bound. We now turn to the precise version of Step 1 from the proof sketch at the beginning of the section.

Lemma 3.6. If $J \in J$ satisfies $\dist(I_\ell, J) \geq |J|$, then

$$|S_\ell(J, \rho) \cap N_\rho Z_{\ell+1}| \lesssim_d \left( \frac{|J|}{|I_\ell|} \right)^{\ell+1-n} |S_\ell(J, 2\rho)|.$$ 

Proof. We first claim that it is possible to cover $S_\ell(J, \rho)$ by a collection $B$ of balls of radius $\rho |J|/|I_\ell|$ with cardinality

$$\#B \lesssim_d \left( \frac{|J|}{\rho |I_\ell|} \right)^n |S_\ell(J, 2\rho)|.$$ 

(13)

Temporarily assuming that this is so, one may argue as follows. For each of the balls $B \in B$ one may apply Wongkew’s theorem [43] (see Theorem A.1) to deduce that

$$|B \cap N_\rho Z_{\ell+1}| \lesssim_d \left( \frac{\rho |J|}{|I_\ell|} \right)^{\ell+1} \rho^{-n(\ell+1)}.$$
Thus, by (13), altogether we find that

\[ |S_\ell(J, \rho) \cap N_\rho \mathbb{Z}_{\ell+1}| \leq \sum_{B \in \mathcal{B}} |B \cap N_\rho \mathbb{Z}_{\ell+1}| \]

\[ \lesssim_d \left( \frac{\rho |J|}{|I_\ell|} \right)^{\ell+1} \rho^{n-(\ell+1)} \left( \frac{|I_\ell|}{\rho |J|} \right)^n |S_\ell(J, 2\rho)|, \]

as desired.

It remains to verify the claim. Letting \( r_\ell := \rho |J|/(4n \ell |I_\ell|) \), by an elementary covering argument it suffices to show that

\[ N_{r_\ell} S_\ell(J, \rho) \cap (\mathbb{R}^{n-1} \times J) \subseteq S_\ell(J, 2\rho). \]  

(14)

Fix a point \( y \in N_{r_\ell} S_\ell(J, \rho) \cap (\mathbb{R}^{n-1} \times J) \) so there exists some \( x \in S_\ell(J, \rho) \) with \( |x - y| < r_\ell \). Furthermore, by the definition of \( S_\ell(J, \rho) \), there exists some \( (a, d) \in Q^{2(n-1)}(\rho) \) and \( t_0 \in J \) such that \( x = l_{a,d}(t_0) \) and \( l_{a,d}(I_{t}) \subseteq N_\rho \mathbb{Z}_j \cap B_{\lambda_j} \). Let \( z \) denote the midpoint of the line segment \( l_{a,d}(I_{t}) \) and \( \theta \) the angle \angle xzy; see Figure 3. The separation between \( J \) and \( I_\ell \) implies that \( |x - z|, |y - z| > |J| \) and therefore

\[ |\tan \theta| \leq \frac{r_\ell}{|J|} = \frac{1}{4n \ell} \cdot \frac{\rho}{|I_\ell|}. \]

(15)

The line passing through \( z \) and \( y \) can be parametrised by \( t \mapsto l_{\tilde{a}, \tilde{d}}(t) \) for some choice of \( (\tilde{a}, \tilde{d}) \in Q^{2(n-1)}(2\rho) \) and \( y = l_{\tilde{a}, \tilde{d}}(t_{1}) \) for some \( t_1 \in J \). Moreover, the angle bound (15) implies that the segment \( l_{\tilde{a}, \tilde{d}}(I_{j}) \) is contained in a \( \rho \)-neighbourhood of \( l_{a,d}(I_j) \) for \( k \leq j \leq \ell \). Thus, \( l_{\tilde{a}, \tilde{d}}(I_j) \subseteq N_{2\rho} \mathbb{Z}_j \cap B_{\lambda_j+2\rho} \) for \( k \leq j \leq \ell \) and, consequently,

\[ y \in l_{\tilde{a}, \tilde{d}}(J) \subseteq S_\ell(J, 2\rho). \]

This establishes (14) and concludes the proof.

**Inductive step: the second bound.** We now turn to the precise version of Step 2 from the proof sketch at the beginning of the section. Loosely speaking, the following lemma tells us that our line segments can never expand at an unexpectedly fast rate, even after leaving the constricted region.

**Lemma 3.7.** If \( J \in \mathcal{J} \) satisfies \( |S_\ell(J, \rho)| \geq 4 |J| \rho^{n-1} \), then

\[ |S_\ell(J, \rho)| \lesssim_d \rho^{-\varepsilon} \left( \frac{|J|}{|I_\ell|} \right)^n |S_\ell(I_\ell, 2\rho)|. \]
To prove Lemma 3.7 we will apply the following elementary lemma which states that, although it is not possible to bound a polynomial at a point in terms of the value that it takes at another point (which could be a root), such a bound holds on average.

**Lemma 3.8.** Let \( P : \mathbb{R} \to \mathbb{R} \) be a polynomial of degree \( m \), \( I \subset \mathbb{R} \) be an interval and \( t \in \mathbb{R} \). Then

\[
|P(t)| \leq \left(8m\max\{|I|, \text{dist}(t, I)\}\right)^{m} \frac{1}{|I|} \int_{I} |P(t')| \, dt'.
\]

The simple proof of this result is postponed until the end of the subsection.

At this point it is also worth recalling that the \( \rho \)-neighbourhoods \( N_{\rho}Z_{j} \) of algebraic varieties \( Z_{j} = Z(P_{1}, \ldots, P_{n-j}) \) are semialgebraic sets. To see this we consider the auxiliary set

\[
Y_{j} = \left\{ (x, y) \in \mathbb{R}^{2n} : P_{1}(x), \ldots, P_{n-j}(x) = 0, |y - x| < \rho \right\}
\]

which is clearly semi-algebraic. Then the Tarski–Seidenberg theorem (see Theorem A.2) tells us that the orthogonal projection \( \Pi(Y_{j}) = N_{\rho}Z_{j} \), where \( \Pi : (x, y) \mapsto y \), is also semi-algebraic with complexity bounded in terms of \( n \) and \( d \).

**Proof (of Lemma 3.7).** Consider slices of \( S_{t}(J, \rho) \) of the form

\[
S_{t}(J, \rho)_{t} := S_{t}(J, \rho) \cap (\mathbb{R}^{n-1} \times \{ t \}), \quad t \in \mathbb{R},
\]

so that, by Fubini’s theorem,

\[
|S_{t}(J, \rho)| \leq 2|J|\rho^{n-1} + \int_{\{t \in J : |S_{t}(J, \rho)_{t}| \geq 2\rho^{n-1}\}} |S_{t}(J, \rho)_{t}| \, dt.
\]

By the hypothesis of the lemma, the first term on the right-hand side is at most half the left-hand term. Therefore, it suffices to prove that

\[
|S_{t}(J, \rho)_{t}| \leq d \rho^{1-\varepsilon} \left(\frac{|J|}{|I_{t}|}\right)^{n-1} |S_{t}(I_{t}, 2\rho)| \frac{|S_{t}(I_{t})|}{|I_{t}|} \tag{16}
\]

whenever \( t \in J \) and \( |S_{t}(J, \rho)_{t}| \geq 2\rho^{n-1} \).

In order to prove (16), we write \( a' = a + t_{t}d \) and \( l'_{a',d}(t) := (a' + (t - t_{t})d, t) \) so that \( l'_{a',d}(t) = l_{a,d}(t) \) and \( S_{t}(J, \rho) \) can be rewritten as

\[
\bigcap_{j=\ell}^{m} \left\{ l'_{a',d}(t) : t \in J, (a' - t_{t}d, d) \in Q^{2(n-1)}(\rho), l'_{a',d}(I_{j}) \subseteq N_{\rho}Z_{j} \cap B_{\lambda_{j}+\rho} \right\}.
\]

Consider the associated sets of lines \( L_{t}(\rho, t_{t}) \equiv L_{t}(\rho, t_{t}, I_{k}, \ldots, I_{m}) \) defined by

\[
L_{t}(\rho, t_{t}) := \bigcap_{j=\ell}^{n} \left\{ (a', d) : (a' - t_{t}d, d) \in Q^{2(n-1)}(\rho), l'_{a',d}(I_{j}) \subseteq N_{\rho}Z_{j} \cap B_{\lambda_{j}+\rho} \right\}.
\]

From the definitions,

\[
(a', d) \in L_{t}(\rho, t_{t}) \quad \text{if and only if} \quad l'_{a',d}(J) \subseteq S_{t}(J, \rho) \tag{17}
\]

and, in particular, if either of these equivalent statements holds, then \( a' \in S_{t}(J, \rho)_{t} \).

Recall from our earlier discussion that the sets \( N_{\rho}Z_{j} \cap B_{\lambda_{j}+\rho} \) are semi-algebraic. By quantifier elimination (that is, the Tarski–Seidenberg theorem), the sets \( L_{t}(\rho, t_{t}) \) are also semi-algebraic (see [25] Lemma 1.1 for an argument of this type). By an application of Lemma 2.2 of [25] (see also Corollary A.3 of the appendix), we can
Figure 4. Forming a semialgebraic section of the lines. Roughly speaking, the slice \( S_\ell(J, \rho)_t \) (shown as a blue vertical line above) is parametrised by a polynomial mapping \( F: \mathbb{R}^{n-1} \to \mathbb{R}^{n-1} \). We can find another polynomial mapping \( G: \mathbb{R}^{n-1} \to \mathbb{R}^{n-1} \) which "selects" a single line through each point \( (F(x), t_\ell) \in S_\ell(J, \rho)_t \). Indeed, the line \( l'_x := \{(F(x) + (t - t_\ell)G(x), t : t \in \mathbb{R}\} \) has this property.

Take a semialgebraic section of \( L_\ell(\rho, t_\ell) \) with complexity bounded by \( C(n, d, \varepsilon) \), so that there is only one direction \( d \) for each possible position \( \mathbf{a}' \) (this is in contrast with [25], where the section was taken to leave only one position for each direction). Calling this section \( L'_{\ell}(\rho, t_\ell) \), we may use Gromov’s algebraic lemma (see Lemma A.4), as in [25, Section 3], to parametrise \( L'_{\ell}(\rho, t_\ell) \). In particular, taking \( s \) to be the first integer larger than \( 2n^2/\varepsilon \), there exists some \( N \in \mathbb{N} \), depending only on the dimension \( n \), degree \( d \) and \( \varepsilon \), and a collection of \( C^s \) functions \( F^i, G^i : [0, 1]^{n-1} \to \mathbb{R}^{n-1} \) for \( 1 \leq i \leq N \) such that:

i) \( \bigcup_{i=1}^{N}(F^i, G^i)([0, 1]^{n-1}) = L'_{\ell}(\rho, t_\ell) \),

ii) \( \sup_{|\alpha| \leq s} \|\partial^\alpha F^i\|_\infty, \sup_{|\alpha| \leq s} \|\partial^\alpha G^i\|_\infty \leq 1, \quad i = 1, \ldots, N. \)

Again following [25, Section 3], we partition \([0, 1]^{n-1}\) into cubes \( Q \) of small diameter \( c\rho^{n/2} \), with \( c \) to be chosen below. On each cube \( Q \), we approximate the \( C^s \) functions \( F^i, G^i : [0, 1]^{n-1} \to \mathbb{R}^{n-1} \) by polynomials \( F^i_Q, G^i_Q : \mathbb{R}^{n-1} \to \mathbb{R}^{n-1} \) of degree \( s \) using Taylor’s theorem. Indeed, letting \( y_Q \) denote the centre of \( Q \), Taylor’s theorem yields polynomials that satisfy

\[
|F^i(y) - F^i_Q(y)|, \quad |G^i(y) - G^i_Q(y)| \leq \frac{1}{s!}|y - y_Q|^s \leq c\rho^{2n}, \quad y \in Q. \tag{18}
\]
Using (17) and unpacking all the definitions,

\[ S_t(J, \rho)_{t_\ell} \subseteq \bigcup_{i=1}^{N} F_i(Q). \]

Furthermore, by (18), the boundary of \( F_i(Q) \) belongs to the \( c^2\rho^{2n} \)-neighbourhood of the boundary of \( F_i(Q) \) and, in particular,

\[ F_i(Q) \subseteq N_{c^2\rho^{2n}}(\partial F_i(Q)) \cup F_i(Q). \]

The set \( F_i(\partial Q) \) is contained in a union of \( 2^n \) algebraic hypersurfaces so that, by Wongkew’s theorem [43] (see Theorem A.1),

\[ |F_i(Q)| \leq C(n, s)c^s\rho^{2n} + |F_i(Q)|. \]

By taking \( c \) sufficiently small, depending only on \( n, d \) and \( \varepsilon \),

\[ |S_t(J, \rho)_{t_\ell}| \leq \rho^{n-1} + \sum_{i=1}^{N} \sum_{Q} |F_i(Q)| \tag{19} \]

and, by the nondegeneracy hypothesis |\( S_t(J, \rho)_{t_\ell} | \geq 2\rho^{n-1} \), we have

\[ |S_t(J, \rho)_{t_\ell}| \leq 2 \sum_{i=1}^{N} \sum_{Q} |S_Q^i(J)_{t_\ell}| \tag{20} \]

where

\[ S_Q^i(J) := \left\{ (F_i^i(y) + (t - t_\ell)G_Q^i(y), t) \in \mathbb{R}^{n-1} \times J : y \in Q \right\}. \]

On the other hand, we also have that \( S_Q^i(I_\ell) \subseteq S_t(I_\ell, 2\rho) \). Indeed, fixing \( y \in Q \), it follows from the definition of the \( F^i \) and \( G^i \), (17) and (18) that

\( (F_i^i(y) + (t - t_\ell)G_Q^i(y), t) \in N_{2\rho}I_j \cap B_{\lambda_j+2\rho} \) for all \( t \in I_j \) and \( k \leq j \leq t \).

In particular, if \( t \in I_\ell \) then \( (F_i^i(y) + (t - t_\ell)G_Q^i(y), t) \in S_t(I_\ell, 2\rho) \). Given that there are fewer than \( C(n, d, \varepsilon)\rho^{-\varepsilon} \) summands in (20), it therefore suffices to show

\[ |S_Q^i(J)_{t_\ell}| \lesssim_d \left( \frac{|J|}{|I_\ell|} \right)^{n-1} \frac{|S_Q^i(I_\ell)|}{|I_\ell|} \tag{21} \]

for any fixed choice of \( i \) and \( Q \). Suppose \( F, G : \mathbb{R}^{n-1} \to \mathbb{R}^{n-1} \) are polynomials of degree at most \( s \) such that \( \det DF \) is not the zero polynomial, where \( DF \) denotes the \((n-1) \times (n-1)\) Jacobian matrix of \( F \). It thus suffices to prove, more generally, that

\[ |S(J)_{t_\ell}| \leq (8(n-1)s)^{n-1} \left( \frac{\max\{|I|, \text{maxdist}(I, J)\}}{|I|} \right)^{n-1} |S(I)| \tag{22} \]

where \( I, J \subseteq \mathbb{R} \) are arbitrary intervals, \( Q \subset [0, 1]^{n-1} \) is any measurable set and

\[ S(I) := \left\{ (F(y) + (t - t_\ell)G(y), t) \in \mathbb{R}^{n-1} \times I : y \in Q \right\}. \]

Indeed, it follows from (19) that the polynomials \( \det DF_Q^i \) are not zero and for the choice of intervals \( I_\ell \) and \( J \) above we have \( \max\{|I_\ell|, \text{maxdist}(I_\ell, J)\} \leq 3|J| \). Hence (21) follows as a special case of (22).

Now, by Bézout’s theorem, \( F + (t - t_\ell)G \) is at most \( s^{n-1} \)-to-one on

\[ Q_\ell = \left\{ y \in Q : \det(DF + (t - t_\ell)DG)(y) \neq 0 \right\}. \]
Furthermore, since, by hypothesis, the polynomial \((y, t) \mapsto \det(DF + tDG)(y)\) is non-zero, it follows by Fubini’s theorem that \(Q \setminus Q_t\) is a Lebesgue null set for almost every \(t \in \mathbb{R}\). Consequently,

\[
\frac{1}{s^{n-1}} \int_I \int_Q |\det(DF + (t-t_e)DG)(y)| \, dy \, dt \leq \int_I |(F + (t-t_e)G)(Q_t)| \, dt \leq |S(I)|.
\]

On the other hand, by an application of Lemma \ref{lem:main}, we have that

\[
|S(J)_{t_e}| = |F(Q)| \leq \int_Q |\det DF(y)| \, dy
\]

\[
\leq (8(n-1))^{-n} \max(|I|, \max\{\text{dist}(I, J)\})^{-n-1} \int_Q \int_I |\det(DF + (t-t_e)DG)(y)| \, dt \, dy.
\]

Combining these displayed inequalities, via an application of Fubini’s theorem, yields \((\ref{eq:final})\) which completes the proof. \(\square\)

**Closing the induction.** By the initial reductions, to close the inductive step (and thereby finish the proof of Lemma \ref{lem:main}), it suffices to show \((\ref{eq:final})\). There are two cases to consider:

- If \(J\) is a subinterval of \((\ref{eq:le})\), then \(|J| = |I_e|\) and \(\max\{\text{dist}(I, J)\} \leq 2|I_e|\). In this case, \((\ref{eq:final})\) immediately follows from Lemma \ref{lem:main}.
- If \(J\) is a subinterval of one of the sets in \((\ref{eq:le})\), then \(\text{dist}(I, J) = |J|\) and \(\max\{\text{dist}(I, J)\} \leq 3|J|\). In this case, \((\ref{eq:final})\) follows from a successive application of Lemma \ref{lem:elementary} and Lemma \ref{lem:main}.

This concludes the proof of Lemma \ref{lem:main}. \(\square\)

**The elementary polynomial bound.** It remains to prove the elementary Lemma \ref{lem:main} which was used in the proof of Lemma \ref{lem:main}.

**Proof (of Lemma \ref{lem:main}).** By translating so that \(I = [-\lambda, \lambda]\) for some \(\lambda > 0\), factorising the resulting polynomial, scaling \(t \to t/\lambda\) and using the fact that the resulting inequality is symmetric over the origin, this reduces to proving

\[
|t - z_1| \cdots |t - z_m| \leq (8m \max\{|t - 1|, 2\})^m \int_{-1}^{1} |(t' - z_1) \cdots (t' - z_m)| \, dt'
\]

whenever \(z_1, \ldots, z_k \in \mathbb{C}\). Supposing that \(|z_1|, \ldots, |z_k| \geq 2\) and \(|z_{k+1}|, \ldots, |z_m| < 2\), as we may, we first note that

\[
\int_{-1}^{1} |(t' - z_1) \cdots (t' - z_m)| \, dt' \geq \left(\frac{1}{2}\right)^k |z_1| \cdots |z_k| \int_{-1}^{1} |(t' - z_{k+1}) \cdots (t' - z_m)| \, dt'
\]

\[
\geq \left(\frac{1}{2}\right)^k |z_1| \cdots |z_k| \left(\frac{1}{2(m-k)}\right)^{m-k}, \quad (\ref{eq:elementary})
\]

where the second inequality follows because most values of \(t' \in [-1, 1]\) must be reasonably far from the roots. Now the small roots, when \(j = k+1, \ldots, m\), satisfy

\[
|t - z_j| \leq |t - 1| + |1 - z_j| \leq 4 \max\{|t - 1|, 2\},
\]

and the large roots, when \(j = 1, \ldots, k\), satisfy

\[
\frac{|z_j|}{|t - z_j|} \geq \frac{|z_j|}{|t - 1| + |1 - z_j|} \geq \min\left\{\frac{|z_j|}{2|t - 1|}, \frac{|z_j|}{2|1 - z_j|}\right\} \geq \frac{1}{2 \max\{|t - 1|, 2\}}.
\]
Together we find that
\[ |z_1| \cdots |z_k| \geq \left( \frac{1}{4 \max(|t-1|, 2)} \right)^m |(t-z_1) \cdots (t-z_m)| \]
which can be plugged into (23) to complete the proof. \qed

3.3. Proof of Theorem 1.4.
Theorem 1.4 now follows by a minor adaptation of the argument from [25], applying Lemma 3.5 in one key step.

Proof (of Theorem 1.4). Note first that when
\[ |T \cap N_{\rho} B_{\lambda_j} \cap N_{\rho} Z_j| \geq \lambda_j |T|, \tag{24} \]
there necessarily exists a line in the direction of $T$ for which the one-dimensional Lebesgue measure of the line intersected with $B_{\lambda_j} \cap N_{\rho} Z_j$ is greater than or equal to $\lambda_j$. By Bézout’s theorem, this line can cross $Z_j$ at most $d$ times, so that if $T \cap B_{\lambda_j} \cap N_{\rho} Z_j$ satisfies (24), it must contain a line segment in the direction of $T$ of length $\lambda_j/(d+1)$. Fattening this line segment, we obtain a truncated $\delta$-tube contained in $B_{\lambda_j} \cap N_{\rho} Z_j$ that projects onto an interval in the $t$-axis of length $\geq \lambda_j/(nd)$. This interval must contain one of the intervals $I_j$ of length $\lambda_j/(2nd)$ with which we partitioned the orthogonal projection of $B_{\lambda_j}$. Recalling that
\[ L_m(2\rho, 0, I_k, \ldots, I_m) := \bigcap_{j=k}^m \left\{ (a, d) \in [-1, 1]^{2(n-1)} : l_{a, d}(I_j) \subseteq N_{2\rho} Z_j \cap B_{\lambda_j} \right\}, \]
we find that
\[ \delta^{-1} \# \bigcap_{j=k}^m \{ T \in \mathbb{T} : |T \cap B_{\lambda_j} \cap N_{\rho} Z_j| \geq \lambda_j |T| \} \lesssim \sum_{I_k, \ldots, I_m} |\Pi(L_m(2\rho, 0, I_k, \ldots, I_m))|, \]
where $\Pi : (a, d) \mapsto d$ denotes the orthogonal projection onto the directions. This is because, for each of the $\delta$-tubes of the original discrete set, there is a whole $\delta$-ball’s worth of different directions contained in one of $\Pi(L_m(2\rho, 0, I_k, \ldots, I_m))$, and these balls finitely overlap due to the fact that $\mathbb{T}$ is direction-separated.

Now by the Tarski–Seidenberg projection theorem, we can take another semi-algebraic section of $L_m(2\rho, 0, I_k, \ldots, I_m)$, this time leaving only one position $a$ for each $a$ as in [25, Lemma 1.2] (see Corollary A.3). Following the notation of [25], we call this section $L'(I_k, \ldots, I_m)$, and so we also have
\[ \delta^{-1} \# \bigcap_{j=k}^m \{ T \in \mathbb{T} : |T \cap B_{\lambda_j} \cap N_{\rho} Z_j| \geq \lambda_j |T| \} \lesssim \sum_{I_k, \ldots, I_m} |\Pi(L'(I_k, \ldots, I_m))|. \tag{25} \]
Noting that there are no more than $(4nd)^{m-k+1}$ summands in this sum, it remains to bound $|\Pi(L'(I_k, \ldots, I_m))|$ independently of the choice of $I_k, \ldots, I_m$. For this we use Gromov’s algebraic lemma as in the previous section to parametrise $L'(I_k, \ldots, I_m)$ with $C^s$ functions $F_i$ and $G_i$:
\[ \bigcup_{i=1}^N (F_i^4, G_i^4)([0, 1]^{n-1}) = L'(I_k, \ldots, I_m). \]
Then we partition $[0, 1]^{n-1}$ into cubes $Q$ again, this time of diameter $c_\varepsilon \varepsilon^{1/n}$, and approximate the functions $F_i$ and $G_i$ by polynomials $F_{Q_i}$ and $G_{Q_i}$ of degree $s \leq C(n, \varepsilon)$ using Taylor’s theorem. Assuming that $|\Pi(L'(I_k, \ldots, I_m))| \geq \delta^{-1}$, as we
may, these polynomial approximations do not alter the total measure significantly and we find that

$$\left| \prod_{i=1}^{N} |G^i_Q(Q)| \right| \leq 2 \sum_{i=1}^{N} \sum_{Q} \left| \det DG^i_Q(y) \right| dy.$$  

For any fixed \( y \in \mathbb{R}^{n-1} \), provided \( \det DG^i_Q(y) \neq 0 \), the polynomial \( t \mapsto \det(DF^i_Q + tDG^i_Q)(y) \) can be expressed as

$$\det DG^i_Q(y) \cdot \prod_{j=1}^{n-1} (t - z_j)$$

for some family of complex roots \( z_1, \ldots, z_{n-1} \in \mathbb{C} \). There exists a subset of \( I_m \) of measure at least \( \lambda_m/2 \) upon which

$$|t - z_j| \geq \frac{\lambda_m}{4(n-1)} \quad \text{for } j = 1, \ldots, n-1.$$  

On this set, it follows that

$$\left| \prod_{i=1}^{N} \int_{I_m} \int_{Q} |\det(DF^i_Q + tDG^i_Q)(y)| dy dt \right| \lesssim N \sum_{i=1}^{N} \sum_{Q} \lambda_m^n |S_m(I_m, 4\rho)|.$$  

Now by an application of Bézout’s theorem as in the previous section, the polynomials \( F^i_Q + tG^i_Q \) are at most \( s^{n-1} \)-to-one, so that each of the integrals on the right-hand side of (26) can be bounded by

$$s^{n-1} \int_{I_m} \left| (F^i_Q + tG^i_Q)(Q) \right| dt \leq s^{n-1} |S_m(I_m, 4\rho)|.$$

Given that there are fewer than \( C(n, d, \varepsilon)\delta^{-\varepsilon} \) summands in (26), this yields

$$\left| \prod_{i=1}^{N} \int_{I_m} \left| (F^i_Q + tG^i_Q)(Q) \right| dt \right| \lesssim d \delta^{-\varepsilon} \lambda_m^n |S_m(I_m, 4\rho)|.$$  

Then the proof is completed by combining this with (25), bounding \( |S_m(I_m, 4\rho)| \) by an application of Lemma 3.3. \( \Box \)

4. Reduction to \( k \)-broad estimates

Rather than attempt to prove (\( K_p \)) directly, it is useful to work with a class of weaker inequalities known as \( k \)-broad estimates. This type of inequality was introduced by Guth [18, 19] in the context of oscillatory integral operators (and, in particular, the Fourier restriction conjecture) and was inspired by the earlier multilinear theory developed in [4] (see also [3] for a detailed discussion of multilinear Kakeya inequalities or Proposition 5.7 below for a precise statement relating the \( k \)-broad and \( k \)-linear theory).

In order to introduce the \( k \)-broad estimates, we decompose the unit sphere \( S^{n-1} \) into finitely-overlapping caps \( \tau \) of diameter \( \beta \), an admissible constant satisfying \( \delta \ll \beta \ll 1 \). We then perform a corresponding decomposition of \( \mathbb{T} \) by writing the family as a disjoint union of subcollections

$$\mathbb{T} = \bigcup_{\tau} \mathbb{T}[\tau]$$
where each $T[\tau]$ satisfies $\text{dir}(T) \in \tau$ for all $T \in T[\tau]$. The ambient euclidean space is also decomposed into tiny balls $B_\delta$ of radius $\delta$. In particular, fix $B_\delta$ a collection of finitely-overlapping $\delta$-balls which cover $\mathbb{R}^n$. For $B_\delta \in B_\delta$ define

$$\mu_T(B_\delta) := \min_{V_1, \ldots, V_n \in \text{Gr}(k-1, n)} \left( \max_{\tau: \angle(\tau, V_\alpha) > \beta \text{ for } 1 \leq \alpha \leq A} \left\| \sum_{T \in T[\tau]} \chi_T \right\|_{L^p(B_\delta)}^p \right),$$

where $A \in \mathbb{N}$ and $\text{Gr}(k-1, n)$ is the Grassmannian manifold of all $(k-1)$-dimensional subspaces in $\mathbb{R}^n$. Here $\angle(\tau, V_\alpha)$ denotes the infimum of the (unsigned) angles $\angle(v, v')$ over all pairs of non-zero vectors $v \in \tau$ and $v' \in V_\alpha$. For $U \subseteq \mathbb{R}^n$ the $k$-broad norm over $U$ is then defined to be

$$\left\| \sum_{T \in T} \chi_T \right\|_{BL_k, A}(U) := \left( \sum_{B_\delta \in B_\delta} \frac{|B_\delta \cap U|}{|B_\delta|} \mu_T(B_\delta) \right)^{1/p}.$$

The $k$-broad norms are not norms in any familiar sense, but they do satisfy weak analogues of various properties of $L^p$-norms. The basic properties of these objects are described in Section 5 below.

The main ingredient in the proof of Theorem 1.2 is the following estimate for $k$-broad norms.

**Theorem 4.1.** Let $p \geq 1 + \frac{2n}{(n-1)n+(k-1)k}$: For all $\varepsilon > 0$, there is an $A \sim 1$ such that

$$\left\| \sum_{T \in T} \chi_T \right\|_{BL_k, A}(\mathbb{R}^n) \lesssim \delta^{-(n-1-n/p) - \varepsilon} \left( \sum_{T \in T} |T| \right)^{1/p} \quad (\text{BL}_k^p)$$

whenever $0 < \delta < 1$ and $T$ is a direction-separated family of $\delta$-tubes.

The proof of Theorem 4.1 which is based on the polynomial partitioning method and closely follows the arguments of [18, 19, 23], will be presented in Sections 5–8.

The key feature which distinguishes the $k$-broad norm from its $L^p$ counterpart is that the former vanishes whenever the tubes of $T$ cluster around a $(k-1)$-dimensional set (see Lemma 5.3 for a precise statement of this property). Owing to this special behaviour, the inequality $(\text{BL}_k^p)$ is substantially weaker than $(K_p)$. Nevertheless, a mechanism introduced by Bourgain and Guth [7] allows one to pass from $k$-broad to linear estimates, albeit under a rather stringent condition on the exponent.

**Proposition 4.2** (Bourgain–Guth [7], Guth [19]). Let $p \geq \frac{n-k+2}{n-k+1}$, $\varepsilon > 0$ and $A \sim 1$. Suppose that

$$\left\| \sum_{T \in T} \chi_T \right\|_{BL_k, A}(\mathbb{R}^n) \lesssim \delta^{-(n-1-n/p)-\varepsilon} \left( \sum_{T \in T} |T| \right)^{1/p} \quad (\text{BL}_k^p)$$

whenever $0 < \delta < 1$ and $T$ is a direction-separated family of $\delta$-tubes. Then

$$\left\| \sum_{T \in T} \chi_T \right\|_{L^p(\mathbb{R}^n)} \lesssim \delta^{-(n-1-n/p)-\varepsilon} \left( \sum_{T \in T} |T| \right)^{1/p} \quad (K_p)$$

whenever $0 < \delta < 1$ and $T$ is a direction-separated family of $\delta$-tubes.

Thus, combining Theorem 4.1 and Proposition 4.2 yields Theorem 1.2. In contrast with the range of Lebesgue exponents in Theorem 4.1 the range in which Proposition 4.2 applies shrinks as $k$ increases. The optimal compromise between the constraints in Theorem 4.1 and Proposition 4.2 is given by [1].
We end this section with a proof of Proposition 4.2 which is a minor modification of the argument in [7] (see also [19]).

**Proof (of Proposition 4.2).** The proof is by an induction-on-scale argument. For the base case, fix $\delta \sim 1$ and let $T$ be a family of direction-separated $\delta$-tubes. If $B$ is a cover of $\mathbb{R}^n$ by finitely-overlapping balls of radius 1, then

$$\left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{L^p(\mathbb{R}^n)}^p \leq \sum_{B \in B} \left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{L^p(B)}^p \lesssim \sum_{B \in B} \# \{ T \in \mathcal{T} : T \subset 3B \}^p.$$

The direction separation condition implies that $\# \mathcal{T} \lesssim 1$ and, consequently, $(K_B)$ follows from Hölder’s inequality and the fact that any tube $T \in \mathcal{T}$ can belong to at most $O(1)$ of the balls $3B$.

Now let $C$ be a fixed constant, chosen sufficiently large so as to satisfy the requirements of the forthcoming argument, and fix some small $\delta > 0$.

**Induction hypothesis:** Suppose the inequality

$$\left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{L^p(\mathbb{R}^n)} \leq C \delta^{-(n-1-n/p)\varepsilon} \left( \sum_{T \in \mathcal{T}} |T| \right)^{1/p}$$

holds whenever $\delta \in [2\delta, 1)$ and $\mathcal{T}$ is a direction-separated family of $\delta$-tubes.

Let $\mathcal{T}$ be a direction-separated family of $\delta$-tubes. Fix a $\delta$-ball $B_\delta \in \mathcal{B}_\delta$ and subspaces $V_1, \ldots, V_A \in \text{Gr}(n, k-1)$ which obtain the minimum in the definition of $\mu_\mathcal{T}(B_\delta)$; thus

$$\mu_\mathcal{T}(B_\delta) = \max_{\tau : V_\tau \geq V_a \geq 0 \text{ for } 1 \leq a \leq A} \left\| \sum_{T \in \mathcal{T}[\tau]} \chi_T \right\|_{L^p(B_\delta)}.$$

Since $A \sim 1$ and $\# \{ \tau : \langle \tau, V_a \rangle \leq \beta \} \sim \beta^{-(k-2)}$, by the triangle inequality followed by Hölder’s inequality,

$$\int_{B_\delta} \left| \sum_{T \in \mathcal{T}} \chi_T \right|^p \lesssim \int_{B_\delta} \sum_{\tau : \langle \tau, V_a \rangle \geq \beta} \sum_{T \in \mathcal{T}[\tau]} \chi_T |^p + \sum_{a=1}^A \int_{B_\delta} \sum_{\tau : \langle \tau, V_a \rangle \leq \beta} \sum_{T \in \mathcal{T}[\tau]} \chi_T |^p$$

$$\lesssim \beta^{-(n-1)p} \mu_\mathcal{T}(B_\delta) + \beta^{-(k-2)(p-1)} \sum_{\tau} \int_{B_\delta} \sum_{T \in \mathcal{T}[\tau]} \chi_T |^p.$$

Summing the estimate over all the balls $B_\delta \in \mathcal{B}_\delta$, we find that

$$\left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{L^p(\mathbb{R}^n)}^p \lesssim \beta^{-(n-1)p} \left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{L^p(B_\delta)}^p + \beta^{-(k-2)(p-1)} \sum_{\tau} \left\| \sum_{T \in \mathcal{T}[\tau]} \chi_T \right\|_{L^p(\mathbb{R}^n)}^p.$$

The first term on the right-hand side of the above display is estimated using the hypothesised broad estimate. For the second term, we apply a linear rescaling $L : \mathbb{R}^n \rightarrow \mathbb{R}^n$ so that

$$\left\| \sum_{T \in \mathcal{T}[\tau]} \chi_T \right\|_{L^p(\mathbb{R}^n)}^p = \beta^{n-1} \left\| \sum_{T \in \mathcal{T}[\tau]} \chi_L(T) \right\|_{L^p(\mathbb{R}^n)}^p$$

(27)

where $\{ L(T) : T \in \mathcal{T}[\tau] \}$ is essentially a collection of $\delta$-tubes with $\delta := \beta^{-1} \delta$. To be more precise, let $\omega \in S^{n-1}$ denote the centre of the cap $\tau$ and choose $L$ so that it fixes the 1-dimensional space spanned by $\omega$ and acts as a dilation by a factor of $\beta^{-1}$.
on the orthogonal complement $\omega^\perp$. Writing $x \in \mathbb{R}^n$ as $x = (x', x_n)$ with $x' \in \omega^\perp$, for any $T \in T[\tau]$ with $v := \text{dir}(T)$ there exists some $u \in \mathbb{R}^n$ such that

$$T \subseteq \{ x \in \mathbb{R}^n : |x' - u' - tv| \lesssim \delta \text{ for some } |t| \leq 1 \text{ and } |x_n - u_n| \leq 1/2 \}.$$  

Applying $L$ one obtains

$$L(T) \subseteq \{ y \in \mathbb{R}^n : |y' - \beta^{-1}u' - t\beta^{-1}v'| \lesssim \beta^{-1}\delta \text{ for some } |t| \leq 1 \text{ and } |y_n - u_n| \leq 1/2 \}$$

and the right-hand side can be covered by a bounded number of $\bar{\delta}$-tubes. Furthermore, the family of $\bar{\delta}$-tubes $L(T)$ is also direction-separated.

Combining (27) with the induction hypothesis we find that

$$\left\| \sum_{T \in \mathcal{T}[\tau]} \chi_T \right\|_{L^p(\mathbb{R}^n)} \lesssim \beta^{-1} C \beta^{(1-\delta)(n-1)p+n+p} \delta^{n-1} \#T[\tau].$$

Recalling that $\sum_{T} \#T[\tau] = \#T$, by plugging the preceding estimate into our $L^p(\mathbb{R}^n)$-norm bound,

$$\left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{L^p(\mathbb{R}^n)} \lesssim C \left( C_{b}(\beta) + C \beta^{(p(n,k)+p)} \right) \delta^{-(n-1)p+n+p} \left( \sum_{T \in \mathcal{T}} |T| \right),$$

where $C_{b}(\beta)$ depends, amongst other things, on the implied constant in [BL1], whilst $C$ is a constant depending only on $n$ and $p$ (and, in particular, is independent of the choice of $\beta$) and

$$e(p,n,k) := (n-k+1)p - (n+k+2).$$

By assumption, $p \geq \frac{n-k+2}{n+k+2}$ and therefore $e(p,n,k) \geq 0$. Consequently, $\beta$ may be chosen sufficiently small, depending only on the admissible parameters $n$, $p$ and $\varepsilon$, so that

$$C \beta^{(p(n,k)+p)} \lesssim \frac{1}{2}.$$

Moreover, if $C$ is chosen sufficiently large from the outset, it follows that

$$\left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{L^p(\mathbb{R}^n)} \lesssim C \delta^{-(n-1)p+n+p} \left( \sum_{T \in \mathcal{T}} |T| \right),$$

which closes the induction and completes the proof. \qed

5. Basic properties of the $k$-broad norms

Vanishing property. The proof of Theorem 4.1 will involve analysing collections of tubes which enjoy certain tangency properties with respect to algebraic varieties.

**Definition 5.1.** Given any collection of polynomials $P_1, \ldots, P_{n-m} : \mathbb{R}^n \to \mathbb{R}$, recall that the common zero set

$$Z(P_1, \ldots, P_{n-m}) := \{ x \in \mathbb{R}^n : P_1(x) = \cdots = P_{n-m}(x) = 0 \}$$

is referred to as a variety. It will often be convenient to work with varieties which satisfy the additional property that

$$\bigwedge_{j=1}^{n-m} \nabla P_j(z) \neq 0 \quad \text{for all } z \in Z = Z(P_1, \ldots, P_{n-m}). \quad (28)$$

In this case the zero set forms a smooth $m$-dimensional submanifold of $\mathbb{R}^n$ with a (classical) tangent space $T_zZ$ at every point $z \in Z$. A variety $Z$ which satisfies (28) is said to be an $m$-dimensional transverse complete intersection.
Definition 5.2. Let $0 < \delta < r < 1$, $x_0 \in \mathbb{R}^n$ and $Z \subseteq \mathbb{R}^n$ be a transverse complete intersection. A $\delta$-tube $T \subseteq \mathbb{R}^n$ is tangent to $Z$ in $B(x_0, r)$ if

i) $T \cap B(x_0, r) \cap N_\delta Z \neq \emptyset$;

ii) If $x \in T$ and $z \in Z \cap B(x_0, 2r)$ satisfy $|z - x| \leq 8\delta$, then

$$\angle(\text{dir}(T), T_z Z) \leq c_{\text{tang}} \frac{\delta}{r}.$$ 

Here $0 < c_{\text{tang}}$ is an admissible constant which is chosen small enough to ensure that, whenever i) and ii) hold,

$$T \cap B(x_0, 2r) \subseteq N_{4\delta} Z.$$  (29)

The fact that such a choice is possible follows from a simple calculus exercise (see, for instance, [20, Proposition 9.2] for details of an argument of this type).

The raison d’être for the $k$-broad norms is the following lemma, which roughly states that the broad norms vanish if the tubes in $T$ cluster around a low dimensional variety.

Lemma 5.3 (Vanishing property). Given $\varepsilon_0 > 0$ and $0 < \beta < 1$ there exists some $0 < c < 1$ such that the following holds. Let $0 < \delta < c$, $r > \delta^{1-\varepsilon_0}$, $x_0 \in \mathbb{R}^n$ and $Z \subseteq \mathbb{R}^n$ be a transverse complete intersection of dimension at most $k - 1$. Then

$$\left\| \sum_{T \in \mathbb{T}} \chi_T \right\|_{\text{BL}_{k, A}(B(x_0, r))} = 0$$

whenever $T$ is a family of $\delta$-tubes which are tangent to $Z$ in $B(x_0, r)$.

Proof. Fix $B_\delta \in B_\delta$ with $B_\delta \cap B(x_0, r) \neq \emptyset$. Recalling the definition of the $k$-broad norm, it suffices to show that there exists some $V \in \text{Gr}(k - 1, n)$ such that

$$\max_{\tau : \angle(\tau, V) > \beta} \int_{B_\delta} \left| \sum_{T \in \mathbb{T} | \tau} \chi_T \right|^p = 0.$$

This would follow if $V$ has the property that

$$\text{if } T \in \mathbb{T} \text{ satisfies } T \cap B_\delta \neq \emptyset, \text{ then } \angle(\text{dir}(T), V) \leq \beta.$$  (30)

Without loss of generality, one may assume there exists some $T_0 \in \mathbb{T}$ such that $T_0 \cap B_\delta \neq \emptyset$ (otherwise (30) vacuously holds for any choice of $(k - 1)$-dimensional subspace). By the containment property resulting from the tangency hypothesis,

$$T_0 \cap B_\delta \subseteq T_0 \cap B(x_0, 2r) \subseteq N_{4\delta} Z$$

and therefore there exists some $z_0 \in Z$ such that $|x_0 - y_0| < 4\delta$ for some $y_0 \in T_0 \cap B_\delta$. Let $V$ be a $(k - 1)$-dimensional subspace containing $T_{z_0} Z$. Given any $T \in \mathbb{T}$, if $x \in T \cap B_\delta$ then $|x - z_0| < 8\delta$ and property ii) of the tangency hypothesis implies

$$\angle(\text{dir}(T), V) \leq \frac{\delta}{r}.$$ 

Since $r > \delta^{1-\varepsilon_0}$, it follows that $\angle(\text{dir}(T), V) \leq \beta$ provided $\delta$ is sufficiently small depending only on $\varepsilon_0$ and $\beta$, which completes the proof. \qed

\footnote{Here the parameter $\beta$ appears implicitly in the definition of the $k$-broad norm.}
Triangle and logarithmic convexity inequalities. The $k$-broad norms satisfy weak variants of certain key properties of $L^p$-norms.

**Lemma 5.4** (Finite subadditivity). Let $U_1, U_2 \subseteq \mathbb{R}^n$, $1 \leq p < \infty$ and $A \in \mathbb{N}$. Then

$$\left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{BL^p_{k,A}(U_1 \cup U_2)}^p \leq \left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{BL^p_{k,A}(U_1)}^p + \left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{BL^p_{k,A}(U_2)}^p$$

whenever $\mathcal{T}$ is a family of $\delta$-tubes.

**Lemma 5.5** (Triangle inequality). Let $U \subseteq \mathbb{R}^n$, $1 \leq p < \infty$ and $A \in \mathbb{N}$. Then

$$\left\| \sum_{T \in \mathcal{T}_1 \cup \mathcal{T}_2} \chi_T \right\|_{BL^p_{k,A}(U)} \leq \left\| \sum_{T \in \mathcal{T}_1} \chi_T \right\|_{BL^p_{k,A}(U)} + \left\| \sum_{T \in \mathcal{T}_2} \chi_T \right\|_{BL^p_{k,A}(U)}$$

whenever $\mathcal{T}_1$ and $\mathcal{T}_2$ are families of $\delta$-tubes.

**Lemma 5.6** (Logarithmic convexity). Let $U \subseteq \mathbb{R}^n$, $1 \leq p, p_0, p_1 < \infty$ and $A \in \mathbb{N}$. Suppose that $\theta \in [0, 1]$ satisfies

$$\frac{1}{p} = \frac{1 - \theta}{p_0} + \frac{\theta}{p_1}.$$

Then

$$\left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{BL^p_{k,A}(U)} \leq \left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{BL^p_{k,A}(U)}^{1 - \theta} \left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{BL^p_{k,A}(U)}^{\theta}$$

whenever $\mathcal{T}$ is a family of $\delta$-tubes.

These estimates are entirely elementary. The proofs are identical to those used to analyse broad norms in the context of the Fourier restriction problem \[19\]. It is remarked that the parameter $A$ appears in the definition of the $k$-broad norm to allow for these weak triangle and logarithmic convexity inequalities.

**$k$-broad versus $k$-linear estimates.** Although not required for the proof of Theorem \[12\] it is perhaps instructive to note the relationship between the $k$-broad norms and the multilinear expressions appearing in the work of Bennett–Carbery–Tao \[4\].

**Proposition 5.7.** Let $\mathcal{T}$ be a collection of $\delta$-tubes in $\mathbb{R}^n$. Then

$$\left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{BL^p_{k,A}(\mathbb{R}^n)} \lesssim \left( \sum_{(\tau_1, \ldots, \tau_k) \sim \beta^{k - 1} - \text{trans.}} \left\| \chi_{N_{i=1}^k T_{j=1}^k[\tau_j]} \right\|_{L^p(\mathbb{R}^n)}^{1/k} \right)^{1/p}$$

where the sum is over all $k$-tuples $(\tau_1, \ldots, \tau_k)$ of caps of diameter $\beta$ which are $\sim \beta^{k - 1}$-transversal in the sense that $| \bigcap_{j=1}^k \omega_j | \gtrsim \beta^{k - 1}$ for all $\omega_j \in \tau_j$.

Thus, any $k$-linear inequality of the type featured in \[4\] \[15\] \[7\] is stronger than the corresponding $k$-broad estimate (given that $\beta$ is admissible).

The proof of Proposition \[5.7\] is a simple exercise and is omitted (see \[20\] for similar results in the (more complicated) context of oscillatory integral operators).
6. Polynomial partitioning

In this section the algebraic and topological ingredients for the proof of Theorem 4.1 are reviewed. In particular, the key polynomial partitioning theorem is recalled, which is adapted from [18, 19] (see also [40]) and previously appeared explicitly in [23].

Given a polynomial \( P : \mathbb{R}^n \to \mathbb{R} \) consider the collection \( \text{cell}(P) \) of connected components of \( \mathbb{R}^n \setminus Z(P) \). Each \( O' \in \text{cell}(P) \) is referred to as a cell cut out by the variety \( Z(P) \) and the cells are thought of as partitioning the ambient euclidean space into a finite collection of disjoint regions.

In order to account for the choice of scale \( \delta > 0 \) appearing in the definition of the \( \delta \)-tubes, it will be useful to consider the family of \( \delta \)-shrunken cells defined by

\[
\mathcal{O} := \{ O' \setminus N_\delta Z(P) : O' \in \text{cell}(P) \}.
\]

An important consequence of this definition is the following simple observation:

A \( \delta \)-tube \( T \) can enter at most \( \deg P + 1 \) of the shrunken cells \( \mathcal{O} \).

Indeed, this is a simple and direct consequence of the fundamental theorem of algebra (or Bézout’s theorem) applied to the core line of \( T \).

**Theorem 6.1** (Guth [19]). Fix \( 0 < \delta < r \), \( x_0 \in \mathbb{R}^n \) and suppose \( F \in L^1(\mathbb{R}^n) \) is non-negative and supported on \( B(x_0, r) \cap N_{4\delta} Z \) where \( Z \) is an \( m \)-dimensional transverse complete intersection with \( \deg Z \leq d \). At least one of the following cases holds:

**Cellular case.** There exists a polynomial \( P : \mathbb{R}^n \to \mathbb{R} \) of degree \( O(d) \) with the following properties:

i) \( \#\text{cell}(P) \sim d^m \) and each \( O \in \text{cell}(P) \) has diameter at most \( r/2 \).

ii) One may pass to a refinement of \( \text{cell}(P) \) such that if \( \mathcal{O} \) is defined as in (31), then

\[
\int_O F \sim d^{-m} \int_{\mathbb{R}^n} F \quad \text{for all } O \in \mathcal{O}.
\]

**Algebraic case.** There exists an \((m - 1)\)-dimensional transverse complete intersection \( Y \) of degree at most \( O(d) \) such that

\[
\int_{B(x_0, r) \cap N_{4\delta} Z} F \lesssim \log d \int_{B(x_0, r) \cap N_{d} Y} F.
\]

This theorem is based on an earlier discrete partitioning result which played a central role in the resolution of the Erdős distance conjecture [21]. The proof is essentially topological, involving the polynomial ham sandwich theorem of Stone–Tukey [36], which is itself a consequence of the Borsuk–Ulam theorem (see, for instance, [32]), combined with a pigeonholing argument.

The theorem is applied to \( k \)-broad norms by taking

\[
F = \sum_{B_i \in B_k} \mu_T(B_i) \frac{1}{|B_i|} \chi_{B_i}.
\]

- If the cellular case holds, then it follows that

\[
\left\| \sum_{T \in \mathcal{O}} \chi_T \right\|_{BL_{k,A}^p(B(x_0, r) \cap N_{4\delta} Z)}^p \lesssim d^m \left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{BL_{k,A}^p(O)}^p \quad \text{for all } O \in \mathcal{O}
\]

where \( \mathcal{O} \) is the collection of cells produced by Theorem 6.1.
If the algebraic case holds, then it follows that
\[ \parallel \sum_{T \in \mathcal{T}} \chi_{T} \parallel_{BL_{k,A}^{p}(B(x_{0},r) \cap N_{\delta} Z)}^{p} \lesssim \log d \parallel \sum_{T \in \mathcal{T}} \chi_{T} \parallel_{BL_{k,A}^{p}(B(x_{0},r) \cap N_{\delta} Y)}^{p} \]
where \( Y \) is the variety produced by Theorem 6.1.

7. Finding polynomial structure

In this section, the recursive argument used to study the Fourier restriction problem in [23] (which, in turn, is adapted from [19]) is reformulated so as to apply to the Kakeya problem. As in [23], the argument will be presented as two separate algorithms:
- \([\text{alg 1}]\) effects a dimensional reduction, essentially passing from an \( m \)-dimensional to an \( (m-1) \)-dimensional situation.
- \([\text{alg 2}]\) consists of repeated application of the first algorithm to reduce to a minimal dimensional case.

The final outcome is a method of decomposing any given \( k \)-broad norm into pieces which are either easily controlled or enjoy special algebraic structure. This decomposition applies to arbitrary families of \( \delta \)-tubes. In the following section, we will specialise to the case where the tube family is direction-separated and use this additional information to prove Theorem 4.1.

The first algorithm. Throughout this section let \( p \geq 1 \) and \( 0 < \varepsilon_{0} \ll \varepsilon \ll 1 \) be fixed.

Input. \([\text{alg 1}]\) will take as its input:
- A choice of small scale \( 0 < \delta \ll 1 \) and large scale \( r_{0} \in [\delta^{1-\varepsilon_{0}}, \delta^{\varepsilon_{0}}] \).
- A transverse complete intersection \( Z \) of dimension \( m \in \{2, \ldots, n\} \).
- A family \( \mathcal{T} \) of \( \delta \)-tubes which are tangent to \( Z \) on a ball \( B_{r_{0}} \) of radius \( r_{0} \).
- A large integer \( A \in \mathbb{N} \).

Output. \([\text{alg 1}]\) will output a finite sequence of sets \( (\mathcal{E}_{j})_{j=0}^{J} \), which are constructed via a recursive process. Each \( \mathcal{E}_{j} \) is referred to as an ensemble and contains all the relevant information coming from the \( j \)th step of the algorithm. In particular, the ensemble \( \mathcal{E}_{j} \) consists of:
- A word \( \mathfrak{h}_{j} \) of length \( j \) in the alphabet \( \{a, c\} \), referred to as a history. The \( a \) is an abbreviation of “algebraic” and \( c \) “cellular”. The words \( \mathfrak{h}_{j} \) are recursively defined by successively adjoining a single letter. Each \( \mathfrak{h}_{j} \) records how the cells \( O_{j} \in \mathcal{E}_{j} \) were constructed via repeated application of the polynomial partitioning theorem.
- A large scale \( r_{j} \in [\delta^{1-\varepsilon_{0}}, \delta^{\varepsilon_{0}}] \). The \( r_{j} \) will in fact be completely determined by the initial scales and the history \( \mathfrak{h}_{j} \). In particular, let \( \sigma_{k} : [0, 1] \to [0, 1] \) be given by
  \[ \sigma_{k}(r) := \begin{cases} \frac{r}{2} & \text{if the } k\text{th letter of } \mathfrak{h}_{j} \text{ is } c \\ r^{1+\varepsilon_{0}} & \text{if the } k\text{th letter of } \mathfrak{h}_{j} \text{ is } a \end{cases} \]
  for each \( 1 \leq k \leq j \). With these definitions,
  \[ r_{j} := \sigma_{j} \circ \cdots \circ \sigma_{1}(r_{0}). \]
Note that each $\sigma_k$ is a decreasing function and
\[
    r_j \leq \delta^c(1+\varepsilon_\circ)^{#a(j)} \quad \text{and} \quad r_j \leq 2^{-#c(j)\delta^c_\circ}
\]
where $#a(j)$ and $#c(j)$ denote the number of occurrences of $a$ and $c$ in the history $h_j$, respectively.

- A family of subsets $O_j$ of $\mathbb{R}^n$ which will be referred to as cells. Each cell $O_j \in \mathcal{O}_j$ is contained in $B_{r_0}$ and will have diameter at most $2r_j$.
- An assignment of a subfamily $T[O_j]$ of $\delta$-tubes to each of the cells $O_j$.
- A large integer $d \in \mathbb{N}$ which depends only on $\deg Z$ and the admissible parameters $n$, $p$ and $\varepsilon$.

Moreover, the components of the ensemble are defined so as to ensure that, for certain coefficients
\[
    C_j(d) := d^{#c(j)\varepsilon_\circ} d^{#a(j)(n+\varepsilon_\circ)}
\]
and $A_j := 2^{-#a(j)} A \in \mathbb{N}$, the following properties hold:

Property I. The function $\sum_{T \in \mathcal{T}} \chi_T$ on $B_{r_0}$ can be compared with functions defined over the $\mathcal{T}[O_j]$:
\[
    \left\| \sum_{T \in \mathcal{T}} \chi_T \right\|^p_{BL^p_{\mathcal{E},A}(B_{r_0})} \leq C_j(d) \sum_{O_j \in \mathcal{O}_j} \left\| \sum_{T \in \mathcal{T}[O_j]} \chi_T \right\|^p_{BL^p_{\mathcal{E},A_j}(O_j)}. \quad (I)_j
\]

Property II. The tube families $\mathcal{T}[O_j]$ satisfy
\[
    \sum_{O_j \in \mathcal{O}_j} \#\mathcal{T}[O_j] \leq C_j(d) d^{#c(j)} \#\mathcal{T}. \quad (II)_j
\]

Property III. Furthermore, each individual $\mathcal{T}[O_j]$ satisfies
\[
    \#\mathcal{T}[O_j] \leq C_j(d) d^{-#c(j)(m-1)} \#\mathcal{T}. \quad (III)_j
\]

The initial step. The initial ensemble $\mathcal{E}_0$ is defined by taking:
- $h := \emptyset$ to be the empty word;
- $r_0$ to be the large scale;
- $O_0$ the collection consisting of the single ball $O_0 := B_{r_0}$;
- $\mathcal{T}[O_0] := \mathcal{T}$.

All the desired properties then vacuously hold.

At this point it is also convenient to fix some large $d \in \mathbb{N}$, to be determined later, which depends only on $\deg Z$ and the admissible parameters $n$, $p$ and $\varepsilon$.

With these definitions, it is trivial to verify that Properties I, II and III hold.

The recursive step. Assume the ensembles $\mathcal{E}_0, \ldots, \mathcal{E}_j$ have been constructed for some $j \in \mathbb{N}_0$ and that they all satisfy the desired properties.
Stopping conditions. The algorithm has two stopping conditions which are labelled \([\text{tiny}]\) and \([\text{tang}]\).

\textbf{Stop: [tiny]} The algorithm terminates if \(r_j \leq \delta^{1-\varepsilon_0}\).

\textbf{Stop: [tang]} Let \(C_{\text{tang}}\) and \(C_{\text{alg}}\) be fixed constants, chosen large enough to satisfy the forthcoming requirements of the proof. The algorithm terminates if the inequalities

\[
\sum_{O_j \in O_j} \left\| \sum_{T \in \mathbb{T}([O_j])} \chi_T \right\|_{BL_{k,A_j}(O_j)}^p \leq C_{\text{tang}} \log d \sum_{S \in S} \left\| \sum_{T \in \mathbb{T}[S]} \chi_T \right\|_{BL_{k,A_j/2}(B[S])}^p
\]

and

\[
\sum_{S \in S} \# \mathbb{T}[S] \leq C_{\text{tang}} \delta^{-\varepsilon_2} \sum_{O_j \in O_j} \# \mathbb{T}[O_j];
\]

\[
\max_{S \in S} \# \mathbb{T}[S] \leq C_{\text{tang}} \max_{O_j \in O_j} \# \mathbb{T}[O_j]
\]

hold for some choice of:

- \(\mathcal{S}\) a collection of transverse complete intersections in \(\mathbb{R}^n\) all of equal dimension \(m-1\) and degree at most \(C_{\text{alg}} d\);
- An assignment of a subfamily \(\mathbb{T}[S]\) of \(\mathcal{T}\) and a \(\max\{r_j^{1+\varepsilon_0}, \delta^{1-\varepsilon_0}\}\)-ball \(B[S]\) to each \(S \in \mathcal{S}\) with the property that each \(T \in \mathbb{T}[S]\) is tangent to \(S\) in \(B[S]\) in the sense of Definition 6.2.

The stopping condition \([\text{tang}]\) can be roughly interpreted as forcing the algorithm to terminate if one can pass to a lower dimensional situation. Indeed, by the inclusion property \([29]\), the broad norm over \(B[S]\) could instead be taken over a \(4\delta\)-neighbourhood of \(S\).

If either of the above conditions hold, then the stopping time is defined to be \(J := j\). Recalling \([42]\), the stopping condition \([\text{tiny}]\) implies that the algorithm must terminate after finitely many steps and, moreover,

\[
\#_a(J) \lesssim \varepsilon_0^{-1} \log(\varepsilon_0^{-1}) \quad \text{and} \quad \#_c(J) \lesssim \log^{-1} d.
\]

Note that there can be relatively few algebraic steps \(#_a(j)\) but there can be many cellular steps \(#_c(j)\). The first of the above estimates can also be used to show that \(C_j(d) \lesssim d^{#_a(J)\varepsilon_0}\) always holds. Furthermore, by choosing \(A \geq 2^{\varepsilon_0^{-2}}\), say, one may ensure that the \(A_j\) defined above are indeed integers.

\textbf{Recursive step.} Suppose that neither stopping condition \([\text{tiny}]\) nor \([\text{tang}]\) is met. One proceeds to construct the ensemble \(\mathcal{E}_{j+1}\) as follows.

Given \(O_j \in O_j\), apply the polynomial partitioning theorem with degree \(d\) to

\[
\left\| \sum_{T \in \mathbb{T}[O_j]} \chi_T \right\|_{BL_{k,A_j}(O_j \cap N_{\varepsilon_0} \mathbb{Z})}^p = \left\| \sum_{T \in \mathbb{T}[O_j]} \chi_T \right\|_{BL_{k,A_j}(O_j)}^p.
\]

For each \(O_j \in \mathcal{O}_j\), either the cellular or the algebraic case holds, as defined in Theorem 6.1. Let \(\mathcal{O}_{j,\text{cell}}\) denote the subcollection of \(\mathcal{O}_j\) consisting of all cells for which the cellular case holds and \(\mathcal{O}_{j,\text{alg}} := \mathcal{O}_j \setminus \mathcal{O}_{j,\text{cell}}\). Thus, by (I), one may bound \(\left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{BL_{k,A}(B_{r_0})}^p\) by

\[
C_j(d) \left[ \sum_{O_j \in \mathcal{O}_{j,\text{cell}}} \left\| \sum_{T \in \mathbb{T}[O_j]} \chi_T \right\|_{BL_{k,A_j}(O_j)}^p + \sum_{O_j \in \mathcal{O}_{j,\text{alg}}} \left\| \sum_{T \in \mathbb{T}[O_j]} \chi_T \right\|_{BL_{k,A_j}(O_j)}^p \right].
\]
the analysis is splits into two cases depending on which term in the above sum dominates.

**Cellular-dominant case.** Suppose that the inequality

$$\sum_{O_j \in \mathcal{O}_{j,\text{alg}}} \left\| \sum_{T \in \mathcal{T}(O_j)} \chi_T \right\|_{BL_{k,A_j}^p(O_j)}^p \leq \sum_{O_j \in \mathcal{O}_{j,\text{cell}}} \left\| \sum_{T \in \mathcal{T}(O_j)} \chi_T \right\|_{BL_{k,A_j}^p(O_j)}^p$$

holds so that

$$\sum_{T \in \mathcal{T}} \chi_T \left\|_{BL_{k,A_j}^p(B_{r_0})}^p \leq 2C_j(d) \sum_{O_j \in \mathcal{O}_{j,\text{cell}}} \left\| \sum_{T \in \mathcal{T}(O_j)} \chi_T \right\|_{BL_{k,A_j}^p(O_j)}^p.$$ (33)

Definition of $\delta_{j+1}$. Define $h_{j+1}$ by adjoining the letter $c$ to the word $h_j$. Thus, it follows from the definitions that

$$r_{j+1} = \frac{1}{2^{r_j}}, \quad \#c(j + 1) = \#c(j) + 1 \quad \text{and} \quad \#a(j + 1) = \#a(j).$$ (34)

The next generation of cells $O_{j+1}$ arise from the cellular decomposition guaranteed by Theorem 6.1. Fix $O_j \in \mathcal{O}_{j,\text{cell}}$ so that there exists some polynomial $P : \mathbb{R}^n \to \mathbb{R}$ of degree $O(d)$ with the following properties:

i) $\#\text{cell}(P) \sim d^{m}$ and each $O \in \text{cell}(P)$ has diameter at most $2r_{j+1}$.

ii) One may pass to a refinement of cell($P$) such that if

$$O_{j+1}(O_j) := \{ O \setminus N_0(Z(P) : O \in \text{cell}(P) \}$$

denotes the corresponding collection of $\delta$-shrunk cells, then

$$\left\| \sum_{T \in \mathcal{T}(O_j)} \chi_T \right\|_{BL_{k,A_j}^p(O_j)}^p \lesssim d^m \left\| \sum_{T \in \mathcal{T}(O_j)} \chi_T \right\|_{BL_{k,A_j}^p(O_{j+1})}^p$$

for all $O_{j+1} \in \mathcal{O}_{j+1}(O_j)$.

Given $O_{j+1} \in \mathcal{O}_{j+1}(O_j)$, define

$$T[O_{j+1}] := \{ T \in T[O_j] : T \cap O_{j+1} \neq \emptyset \}.$$ (35)

Recall that, by the fundamental theorem of algebra (or Bézout’s theorem), any $\delta$-tube $T$ can enter at most $O(d)$ cells $O_{j+1} \in \mathcal{O}_{j+1}(O_j)$ and, consequently,

$$\sum_{O_{j+1} \in \mathcal{O}_{j+1}(O_j)} \#T[O_{j+1}] \lesssim d \cdot \#T[O_j].$$ (35)

By the pigeonhole principle, one may pass to a refinement of $\mathcal{O}_{j+1}(O_j)$ such that

$$\#T[O_{j+1}] \lesssim d^{-(m-1)} \#T[O_j] \quad \text{for all } O_{j+1} \in \mathcal{O}_{j+1}(O_j).$$ (36)

Finally, define

$$O_{j+1} := \bigcup_{O_j \in \mathcal{O}_{j,\text{cell}}} O_{j+1}(O_j).$$

This completes the construction of $\delta_{j+1}$ and it remains to check that the new ensemble satisfies the desired properties. In view of this, it is useful to note that

$$C_j(d) = d^{-e}C_{j+1}(d) \quad \text{and} \quad A_j = A_{j+1},$$ (37)

which follows immediately from (54) and the definition of the $C_j(d)$ and $A_j$. 

\*
Property I. Fix $O_j \in \mathcal{O}_{j,\text{cell}}$ and observe that $\#\mathcal{O}_{j+1}(O_j) \sim d^m$ and
\[
\left\| \sum_{T \in \mathcal{T}[O_j]} \chi_T \right\|_{BL_k^p A_j(O_j)}^p \lesssim d^m \left\| \sum_{T \in \mathcal{T}[O_{j+1}]} \chi_T \right\|_{BL_k^p A_j(O_{j+1})}^p
\]
for all $O_{j+1} \in \mathcal{O}_{j+1}(O_j)$. Averaging,
\[
\left\| \sum_{T \in \mathcal{T}[O_j]} \chi_T \right\|_{BL_k^p A_j(O_j)}^p \lesssim \sum_{O_{j+1} \in \mathcal{O}_{j+1}(O_j)} \left\| \sum_{T \in \mathcal{T}[O_{j+1}]} \chi_T \right\|_{BL_k^p A_j(O_{j+1})}^p
\]
and, recalling (33) and (37), one deduces that
\[
\left\| \sum_{T \in \mathcal{T}[O_j]} \chi_T \right\|_{BL_k^p A_j(B_{\alpha})}^p \lesssim C d^{-\varepsilon_0} C_{j+1}(d) \sum_{O_{j+1} \in \mathcal{O}_{j+1}} \left\| \sum_{T \in \mathcal{T}[O_{j+1}]} \chi_T \right\|_{BL_k^p A_j(O_{j+1})}^p.
\]
Provided $d$ is chosen large enough so as to ensure that the additional $d^{-\varepsilon_0}$ factor absorbs the unwanted constant $C$, one deduces (I)$_{j+1}$. This should be compared with the approach of Solymosi and Tao to polynomial partitioning [35].

Property II. By the construction,
\[
\sum_{O_{j+1} \in \mathcal{O}_{j+1}} \#\mathcal{T}[O_{j+1}] = \sum_{O_j \in \mathcal{O}_j} \sum_{O_{j+1} \in \mathcal{O}_{j+1}(O_j)} \#\mathcal{T}[O_{j+1}] \lesssim d \sum_{O_j \in \mathcal{O}_j} \#\mathcal{T}[O_j],
\]
where the inequality follows from a term-wise application of (33). Thus, (II)$_j$, (34) and (37) imply that
\[
\sum_{O_{j+1} \in \mathcal{O}_{j+1}} \#\mathcal{T}[O_{j+1}] \lesssim d^{-\varepsilon_0} C_{j+1}(d) d^{\#\mathcal{T}[O_{j+1}]}.\]
Provided $d$ is chosen sufficiently large, one deduces (II)$_{j+1}$.

Property III. Fix $O_{j+1} \in \mathcal{O}_{j+1}(O_j)$ and recall from (36) that
\[
\#\mathcal{T}[O_{j+1}] \lesssim d^{-(m-1)} \#\mathcal{T}[O_j].
\]
Thus, (III)$_j$, (34) and (37) imply that
\[
\#\mathcal{T}[O_{j+1}] \lesssim d^{-\varepsilon_0} C_{j+1}(d) d^{-\#\mathcal{T}[O_j]}.
\]
Provided $d$ is chosen sufficiently large as before, one deduces (III)$_{j+1}$.

**Algebraic-dominant case.** Suppose the hypothesis of the cellular-dominant case fails so that
\[
\left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{BL_k^p A_j(B_{\alpha})}^p \lesssim 2C_j(d) \sum_{O_j \in \mathcal{O}_{j,\text{alg}}} \left\| \sum_{T \in \mathcal{T}[O_j]} \chi_T \right\|_{BL_k^p A_j(O_j)}^p. \tag{38}
\]
Each cell in $O_{j,\text{alg}}$ satisfies the condition of the algebraic case of Theorem 6.1 this information is used to construct the $(j+1)$-generation ensemble.
Definition of $\ell_j^{+1}$. Define $h_j$ by adjoining the letter $a$ to the word $h_j$. Thus, it follows from the definitions that

$$r_j^{+1} = r_j^{1+\varepsilon_c}, \quad \#c(j + 1) = \#c(j) \quad \text{and} \quad \#a(j + 1) = \#a(j) + 1.$$  

(39)

The next generation of cells is constructed from the varieties which arise from the algebraic case in Theorem [6.3]. Fix $O_j \in \mathcal{O}_{j,\text{alg}}$ so that there exists a transverse complete intersection $Y_j$ of dimension $m - 1$ and deg $Y_j \leq C_{\text{alg}}d$ such that

$$\left\| \sum_{T \in \mathcal{T}[O_j]} \chi_T \right\|_{\text{BL}_{\varepsilon}^{\mathcal{A}_j}(O_j)}^p \lesssim \log d \left\| \sum_{T \in \mathcal{T}[O_j]} \chi_T \right\|_{\text{BL}_{\varepsilon}^{\mathcal{A}_j}(O_j \cap N_\delta Y_j)}^p.$$  

Let $B(O_j)$ be a cover of $O_j \cap N_\delta Y_j$ consisting of finitely-overlapping balls of radius $\max\{r_{j+1}, \delta^{1-\varepsilon_c}\}$. For each $B \in B(O_j)$ let $T_B$ denote the family of $T \in \mathcal{T}[O_j]$ for which $T \cap B \cap N_\delta Y_j \neq \emptyset$. This set is partitioned into the subsets

$$\mathcal{T}_B, \text{tang} := \{ T \in \mathcal{T}_B : T \text{ is tangent to } Y_j \text{ on } B \}, \quad \mathcal{T}_B, \text{trans} := \mathcal{T}_B \setminus \mathcal{T}_B, \text{tang};$$

here the notion of tangency is that given in Definition [5.2].

By hypothesis, $[\text{tang}]$ fails and, consequently, one may deduce that

$$\sum_{O_j \in \mathcal{O}_{j,\text{alg}}} \left| \sum_{T \in \mathcal{T}[O_j]} \chi_T \right|_{\text{BL}_{\varepsilon}^{\mathcal{A}_j}(O_j)}^p \lesssim \log d \sum_{O_j \in \mathcal{O}_{j,\text{alg}}} \left| \sum_{T \in \mathcal{T}_B, \text{trans}} \chi_T \right|_{\text{BL}_{\varepsilon}^{\mathcal{A}_j+1}(B_j)}^p$$  

(40)

where, for notational convenience, $B_j := B \cap N_\delta Y_j$. Indeed, provided $C_{\text{tang}} > 0$ is sufficiently large,

$$\sum_{O_j \in \mathcal{O}_{j,\text{alg}}} \sum_{B \in B(O_j)} \#\mathcal{T}_B, \text{tang} \leq C_{\text{tang}} \delta^{-n\varepsilon_c} \sum_{O_j \in \mathcal{O}_j} \#\mathcal{T}[O_j];$$

$$\max_{O_j \in \mathcal{O}_{j,\text{alg}}} \max_{B \in B(O_j)} \#\mathcal{T}_B, \text{tang} \leq \max_{O_j \in \mathcal{O}_j} \#\mathcal{T}[O_j].$$  

(41)

Consequently, the failure of the stopping condition $[\text{tang}]$ forces

$$\log d \sum_{O_j \in \mathcal{O}_{j,\text{alg}}} \sum_{B \in B(O_j)} \left| \sum_{T \in \mathcal{T}_B, \text{tang}} \chi_T \right|_{\text{BL}_{\varepsilon}^{\mathcal{A}_j+1}(B)}^p \lesssim \frac{1}{C_{\text{tang}}} \sum_{O_j \in \mathcal{O}_j} \sum_{T \in \mathcal{T}[O_j]} \left| \sum_{T \in \mathcal{T}_B, \text{tang}} \chi_T \right|_{\text{BL}_{\varepsilon}^{\mathcal{A}_j}(O_j)}^p$$

(since the estimates in [41] show all other conditions for $[\text{tang}]$ are met for $\mathcal{S}$, $\mathcal{T}[S]$ and $B[S]$ appropriately defined). On the other hand, by the triangle inequality for broad norms (Lemma [5.5]), using the fact that $A_{j+1} = A_j/2$, the left-hand side of (40) is dominated by

$$\log d \sum_{O_j \in \mathcal{O}_{j,\text{alg}}} \sum_{B \in B(O_j)} \left[ \left| \sum_{T \in \mathcal{T}_B, \text{tang}} \chi_T \right|_{\text{BL}_{\varepsilon}^{\mathcal{A}_j+1}(B_j)}^p + \left| \sum_{T \in \mathcal{T}_B, \text{trans}} \chi_T \right|_{\text{BL}_{\varepsilon}^{\mathcal{A}_j+1}(B_j)}^p \right].$$

For a suitable choice of constant $C_{\text{tang}}$, combining the information in the two previous displays yields (40).

For $O_j \in \mathcal{O}_{j,\text{alg}}$ define

$$O_{j+1}(O_j) := \{ B \cap N_\delta Y_j : B \in B(O_j) \}$$

and let $\mathcal{T}[O_{j+1}] := \mathcal{T}_B, \text{trans}$ for $O_{j+1} = B \cap N_\delta Y_j \in \mathcal{O}_{j+1}(O_j)$. The collection of cells $O_{j+1}$ is then given by

$$O_{j+1} := \bigcup_{O_j \in \mathcal{O}_{j,\text{alg}}} O_{j+1}(O_j).$$
It remains to verify that the ensemble $\mathcal{E}_{j+1}$ satisfies the desired properties. In view of this, it is useful to note that

$$C_j(d) = d^{-(n+\varepsilon)}C_{j+1}(d),$$

which follows directly from the definition of $C_j(d)$ and (39).

**Property I.** By combining (40) together with the various definitions one obtains

$$\sum_{O_j \in \mathcal{O}_{j,\text{alg}}} \# \mathcal{T}(O_j) \leq \log d \sum_{O_{j+1} \in \mathcal{O}_{j+1}} \# \mathcal{T}(O_{j+1}) \sum_{T \in \mathcal{T}(O_{j+1})} \chi_T \left| \sum_{B \in \mathcal{B}(O_j)} \chi_B \right| \left( \sum_{B \in \mathcal{B}(O_j)} \chi_B \right)^p \left( \sum_{B \in \mathcal{B}(O_{j+1})} \chi_B \right)^p.$$  

Recalling (68) and (12), if $c(d) := C d^{-(n+\varepsilon)} \log d$ for an appropriate choice of admissible constant $C$, then

$$\sum_{T \in \mathcal{T}} \chi_T \left( \sum_{B \in \mathcal{B}(O_j)} \chi_B \right)^p \leq c(d) C_{j+1}(d) \sum_{O_{j+1} \in \mathcal{O}_{j+1}} \# \mathcal{T}(O_{j+1}) \sum_{T \in \mathcal{T}(O_{j+1})} \chi_T \left( \sum_{B \in \mathcal{B}(O_j)} \chi_B \right)^p \left( \sum_{B \in \mathcal{B}(O_{j+1})} \chi_B \right)^p.$$  

Provided $d$ is sufficiently large, $c(d) \leq 1$ and one thereby deduces (I)$_{j+1}$.

**Property II.** Fix $O_j \in \mathcal{O}_{j,\text{alg}}$ and note that

$$\sum_{O_{j+1} \in \mathcal{O}_{j+1}(O_j)} \# \mathcal{T}(O_{j+1}) = \sum_{B \in \mathcal{B}(O_j)} \# \mathcal{T}_{B,\text{trans}}$$

by the definition of $\mathcal{T}(O_{j+1})$. To estimate the latter sum one may invoke the following algebraic-geometric result of Guth, which appears in Lemma 5.7 of [19].

**Lemma 7.1** ([19]). Suppose $T$ is an infinite cylinder in $\mathbb{R}^n$ of radius $\delta$ and central axis $\ell$ and $Y$ is a transverse complete intersection. For $\alpha > 0$ let

$$Y_{> \alpha} := \{ y \in Y : \angle(\ell, Y, y) > \alpha \}.$$  

The set $Y_{> \alpha} \cap T$ is contained in a union of $\mathcal{O}(\deg Y^n)$ balls of radius $\delta \alpha^{-1}$.

Since $T \cap B \cap N_2 Y \neq \emptyset$ by the definition of $\mathcal{T}_B$, a tube $T \in \mathcal{T}_{B,\text{trans}}$ if and only if the angle condition ii) from Definition 5.2 fails to be satisfied. Thus, given any $T \in \bigcup_{B \in \mathcal{B}} \mathcal{T}_{B,\text{trans}}$, it follows from the definitions that

$$\angle(\text{dir}(T), T_y Y) \geq \frac{\delta}{r_{j+1}}$$

for some $y \in Y \cap 2B$ with $|y - x| \leq \delta$ for some $x \in T$. This implies that

$$N_{C_{j}} T \cap 2B \cap Y_{> \alpha_{j+1}} \neq \emptyset$$

where $\alpha_{j+1} \sim \delta/r_{j+1}$. Consequently, by Lemma 7.1 any $T \in \bigcup_{B \in \mathcal{B}(O_j)} \mathcal{T}_{B,\text{trans}}$ lies in at most $O(d^n)$ of the sets $\mathcal{T}_{B,\text{trans}}$ and so

$$\sum_{B \in \mathcal{B}(O_j)} \# \mathcal{T}_{B,\text{trans}} \lesssim d^n \# \mathcal{T}(O_j).$$

Combining this inequality with (13) and summing over all $O_j \in \mathcal{O}_{j,\text{alg}},$

$$\sum_{O_{j+1} \in \mathcal{O}_{j+1}} \# \mathcal{T}(O_{j+1}) \lesssim d^n \sum_{O_j \in \mathcal{O}_j} \# \mathcal{T}(O_j).$$
Applying (II), (39) and (42), one concludes that
\[ \sum_{O_{j+1} \in \mathcal{O}_{j+1}} \# \mathcal{T}[O_{j+1}] \lesssim d^{-\varepsilon} C_{j+1}(d) d^{#(j+1)} \mathcal{T}. \]

Provided \( d \) is chosen to be sufficiently large to absorb the implicit constant, one deduces (II)_{j+1}.

**Property III.** Fix \( O_j \in \mathcal{O}_{j, \text{alg}} \) and \( O_{j+1} \in \mathcal{O}_{j+1}(O_j) \). By definition, \( \mathcal{T}[O_{j+1}] \subseteq \mathcal{T}[O_j] \) and so
\[ \# \mathcal{T}[O_{j+1}] \leq \# \mathcal{T}[O_j] \leq C_{j+1}(d) d^{-\#(j+1)(m-1)} \mathcal{T}, \]
by (III)_j and (39).

**The second algorithm.** The algorithm [alg 1] is now applied repeatedly in order to arrive at a final decomposition of the \( k \)-broad norm. This process forms part of a second algorithm, referred to as [alg 2].

Throughout this section let \( p_\ell \), with \( k \leq \ell \leq n \), denote some choice of Lebesgue exponents satisfying \( p_k \geq p_{k+1} \geq \ldots \geq p_n =: p \geq 1 \). The numbers \( 0 \leq \Theta_\ell \leq 1 \) are then defined in terms of the \( p_\ell \) by
\[ \Theta_\ell := (1 - \frac{1}{p_\ell})^{-1} \left( 1 - \frac{1}{p} \right) \]
so that \( \Theta_n = 1 \). Also fix \( 0 < \varepsilon_0 \ll \varepsilon \ll 1 \) as in the previous section.

There are two stages to [alg 2], which can roughly be described as follows:

- **The recursive stage:** \( \sum_{T \in \mathcal{T}} \chi_T \) is repeatedly decomposed into pieces with favourable tangency properties with respect to varieties of progressively lower dimension.
- **The final stage:** \( \sum_{T \in \mathcal{T}} \chi_T \) is further decomposed into very small scale pieces.

To begin, the recursive stage of [alg 2] is described.

**Input.** [alg 2] will take as its input:
- A choice of small scale \( 0 < \delta \ll 1 \).
- A large integer \( A \in \mathbb{N} \).
- A family of \( \delta \)-tubes \( T \) which are non-degenerate in the sense that
\[ \left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{\text{BL}_{k,A}^p} \neq 0. \] (44)

Note that the process applies to essentially arbitrary families of \( \delta \)-tubes (in particular, the direction-separated hypothesis does not appear at this stage).

**Output.** The \((n + 1 - \ell)\)th step of the recursion will produce:
- An \((n + 1 - \ell)\)-tuple of:
  - scales \( \delta_\ell = (\delta_n, \ldots, \delta_\ell) \) satisfying \( \delta^{\varepsilon_\ell} = \delta_n > \cdots > \delta_\ell \geq \delta^{1 - \varepsilon_\ell} \);
  - large and (in general) non-admissible parameters \( D_\ell = (D_n, \ldots, D_\ell) \);
  - integers \( A = (A_n, \ldots, A_\ell) \) satisfying \( A_n > A_{n-1} > \cdots > A_\ell \).
Each of these \((n + 1 - \ell)\)-tuples is formed by adjoining a component to the corresponding \((n - \ell)\)-tuple from the previous stage.
A family $\vec{S}_\ell$ of $(n + 1 - \ell)$-tuples of transverse complete intersections $\vec{S}_\ell = (S_{n, \ldots, S_\ell})$ satisfying $\dim S_i = i$ and $\deg S_i = O(1)$ for $\ell \leq i \leq n$.

- An assignment of a $\delta_i$-ball $B[\vec{S}_\ell]$ and a subfamily $T[\vec{S}_\ell]$ of $\delta$-tubes to each $\vec{S}_\ell \in \vec{S}_\ell$ with the property that the tubes $T \in T[\vec{S}_\ell]$ are tangent to $S_\ell$ in $B[\vec{S}_\ell]$ (here $S_\ell$ is the final component of $\vec{S}_\ell$).

This data is chosen so that the following properties hold:

**Notation.** Throughout this section a large number of harmless $\delta^{-\varepsilon_\ell}$-factors appear in the inequalities. For notational convenience, given $A, B \geq 0$ let $A \lesssim B$ or $B \gtrsim A$ denote $A \lesssim \delta^{-\varepsilon_\ell} B$ for some $c > 0$ depending only on $n$ and $p$.

**Property 1.** The inequality

$$\left\| \sum_{T \in T} \chi_T \right\| \text{BL}_{k, A}(\mathbb{R}^n) \lesssim C(D_\ell; \vec{\delta}_\ell)[\delta^n \# T]^{1 - \Theta_1} \left( \sum_{\vec{S}_\ell \in \vec{S}_\ell} \sum_{T \in T[\vec{S}_\ell]} \chi_T \right)^{\frac{p_1}{p_2}}$$

holds for

$$C(D_\ell; \vec{\delta}_\ell) := \prod_{i = \ell}^{n-1} \left( \frac{\delta_i}{\delta} \right)^{\Theta_{i+1} - \Theta_i} D_i^{(1 + \varepsilon_\ell)(\Theta_{i+1} - \Theta_i) + \varepsilon_\ell}.$$  \hspace{1cm} (45)

**Property 2.** For $\ell \leq n - 1$, the inequality

$$\sum_{\vec{S}_\ell \in \vec{S}_\ell} \# T[\vec{S}_\ell] \lesssim D_\ell^{1 + \varepsilon_\ell} \sum_{\vec{S}_{\ell + 1} \in \vec{S}_{\ell + 1}} \# T[\vec{S}_{\ell + 1}]$$

holds.

**Property 3.** For $\ell \leq n - 1$, the inequality

$$\max_{\vec{S}_\ell \in \vec{S}_\ell} \# T[\vec{S}_\ell] \lesssim D_\ell^{-\ell + \varepsilon_\ell} \max_{\vec{S}_{\ell + 1} \in \vec{S}_{\ell + 1}} \# T[\vec{S}_{\ell + 1}]$$

holds.

By the inclusion property (29), the broad norms over $B[\vec{S}_\ell]$ on the right-hand side of (45) could be replaced by broad norms over $4\delta$-neighbourhoods of $S_\ell$.

**First step.** Vacuously, the tubes belonging to $T$ are tangent to the $n$-dimensional variety $\mathbb{R}^n$. Let $B_\circ$ denote a collection of finitely-overlapping balls of radius $\delta_\circ$ which cover $\bigcup_{T \in T} T$ and define

- $\delta := \delta_\circ; \; D_0 := 1$ and $A_0 := A$;
- $S_\circ$ is the collection consisting of repeated copies of the 1-tuple $(\mathbb{R}^n)$, with one copy for each ball in $B_\circ$;
- For each $\vec{S}_n \in S_n$ assign a ball $B[\vec{S}_n] \in B_\circ$ and let

$$T[\vec{S}_n] := \{ T \in T : T \cap B[\vec{S}_n] \neq \emptyset \}.$$

By a straightforward orthogonality argument (identical to that used to establish the base case in the proof of Proposition 1), Property 1 can be shown to hold with $C(D_\circ; \vec{\delta}_\circ) = 1$ and $\Theta_n = 1$. 

If $n + 2 - \ell$th step. Let $\ell \geq 1$ and suppose that the recursive algorithm has run through $n + 1 - \ell$ steps. Since each family $T[\tilde{S}_1]$ consists of $\delta$-tubes which are tangent to $\tilde{S}_1$ on $B[\tilde{S}_1]$, one may apply $[\text{alg 1}]$ to bound the $k$-broad norm

$$\left\| \sum_{T \in T[\tilde{S}_1]} \chi_T \right\|_{B_{k,A_1}^p(B[\tilde{S}_1])},$$

which is denoted by $[\text{tiny-dom}]$. One of two things can happen: either $[\text{alg 1}]$ terminates due to the stopping condition $[\text{tiny}]$ or it terminates due to the stopping condition $[\text{tang}]$. The current recursive process terminates if the contributions from terms of the former type dominate:

**Stopping condition.** The recursive stage of $[\text{alg 2}]$ has a single stopping condition, which is denoted by $[\text{tiny-dom}].$

**Stop:** $[\text{tiny-dom}]$ Suppose that the condition $[\text{tiny-dom}]$ is not met. Necessarily,

$$\left\| \sum_{\tilde{S}_1 \in \tilde{S}_1} \sum_{T \in T[\tilde{S}_1]} \chi_T \right\|_{B_{k,A_1}^p(B[\tilde{S}_1])} \leq 2 \sum_{\tilde{S}_1 \in \tilde{S}_1, \text{tiny}} \sum_{T \in T[\tilde{S}_1]} \chi_T \right\|_{B_{k,A_1}^p(B[\tilde{S}_1])},$$

where the right-hand summation is restricted to those $\tilde{S}_1 \in \tilde{S}_1$ for which $[\text{alg 1}]$ terminates owing to the stopping condition $[\text{tiny}]$. Then $[\text{alg 2}]$ terminates.

Assume that the condition $[\text{tiny-dom}]$ is not met. Necessarily,

$$\left\| \sum_{\tilde{S}_1 \in \tilde{S}_1} \sum_{T \in T[\tilde{S}_1]} \chi_T \right\|_{B_{k,A_1}^p(B[\tilde{S}_1])} \leq 2 \sum_{\tilde{S}_1 \in \tilde{S}_1, \text{tang}} \sum_{T \in T[\tilde{S}_1]} \chi_T \right\|_{B_{k,A_1}^p(B[\tilde{S}_1])},$$

where the right-hand summation is restricted to those $\tilde{S}_1 \in \tilde{S}_1$ for which $[\text{alg 1}]$ does not terminate owing to $[\text{tiny}]$ and therefore terminates owing to $[\text{tang}]$.

Consequently, for each $\tilde{S}_1 \in \tilde{S}_1, \text{tang}$ the inequalities

$$\left\| \sum_{T \in T[\tilde{S}_1]} \chi_T \right\|_{B_{k,A_1}^p(B[\tilde{S}_1])} \leq D_{t-1} \sum_{\tilde{S}_1 \in \tilde{S}_1} \sum_{T \in T[\tilde{S}_1]} \chi_T \right\|_{B_{k,A_1}^p(B[\tilde{S}_1])},$$

and

$$\sum_{S_{t-1} \in S_{t-1} | S_t \text{tang}} \#T[S_{t-1}] \leq D_{t-1}^{1+\varepsilon} \#T[S_t];$$

(49)

$$\max_{S_{t-1} \in S_{t-1} | S_t \text{tang}} \#T[S_{t-1}] \leq D_{t-1}^{-(t-1)+\varepsilon} \#T[S_t]$$

(50)

hold for some choice of:

- Scale $\delta_{t-1}$ satisfying $\delta_t > \delta_{t-1} \geq \delta^{1-\varepsilon}$; non-admissible number $D_{t-1}$ and large integer $A_{t-1}$ satisfying $A_{t-1} \sim A_t$;
- Family $S_{t-1}[\tilde{S}_1]$ of $(t-1)$-dimensional transverse complete intersections of degree $O(1)$;
- Assignment of a subfamily $T[S_{t-2} | S_{t-1}] = T[\tilde{S}_1 | S_{t-1}]$ of $\delta$-tubes for every $S_{t-1} \in S_{t-1}[\tilde{S}_1]$ such that each $T \in T[S_{t-1}]$ is tangent to $S_{t-1}$ on $B[\tilde{S}_1 \text{tang}].$
Each inequality (15), (19) and (31) is obtained by combining the definition of the stopping condition [tang] with Properties I, II and III from [alg 1], respectively. Indeed, we take

$$r_0 := \delta_1, \quad \delta_{t-1} := \max\{r_0^{1+\varepsilon_0}, \delta^{1-\varepsilon_0}\}, \quad \text{and} \quad D_{t-1} := d#\varepsilon(J),$$

using the notation from [alg 1].

The $\delta_{t-1}$, $D_{t-1}$ and $A_{t-1}$ can depend on the choice of $S_t$, but this dependence can be essentially removed by pigeonholing. In particular, $#\varepsilon(J)$ depends on $S_t$, but satisfies $#\varepsilon(J) = O(\log \delta^{-1})$. Thus, since there are only logarithmically many possible different values, one may find a subset of the $S_t,\varepsilon$ over which the $D_{t-1}$ all have a common value and, moreover, the inequality (46) still holds except that the constant $1/2$ is now replaced with, say, $\delta^{-\varepsilon_0}$. A brief inspection of [alg 1] shows that both $\delta_{t-1}$ and $A_{t-1}$ are determined by $D_{t-1}$ and so the desired uniformity is immediately inherited by these parameters.

Letting $\bar{S}_{t-1}$ denote the structured set

$$\bar{S}_{t-1} := \{ (\bar{S}_t, S_{t-1}) : \bar{S}_t \in \bar{S}_{t,\varepsilon} \text{ and } S_{t-1} \in S_{t-1}[\bar{S}_t] \},$$

where $\bar{S}_{t,\varepsilon}$ is understood to be the refined collection described in the previous paragraph, it remains to verify that the desired properties hold for the newly constructed data. Property 2 follows immediately from (49) and Property 3 from (50), so it remains only to verify Property 1.

By combining the inequality (45) from the previous stage of the algorithm with (47) and (48), one deduces that

$$\left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{L^p_{k,M}(\mathbb{R}^n)} \leq D_{t-1}^p C(\bar{D}_t; \bar{S}_t)(\delta^n #\mathcal{T})^{1-\Theta_t} \left\| \sum_{T \in \mathcal{T}[\bar{S}_{t-1}]} \chi_T \right\|_{p_{t-1}L^p_{k,M}(\mathbb{R}^n, \bar{S}_{t-1})}$$

where, for any $1 \leq q < \infty$ and $M \in \mathbb{N}$, we write

$$\left\| \sum_{T \in \mathcal{T}[\bar{S}_{t-1}]} \chi_T \right\|_{L^p_{k,M}(\mathbb{R}^n, \bar{S}_{t-1})} := \left( \sum_{T \in \mathcal{T}[\bar{S}_{t-1}]} \left( \sum_{T \in \mathcal{T}[\bar{S}_{t-1}]} \chi_T \right)^q \right)^{1/q} .$$

Taking $q = p_t$ and $M = 2A_{t-1}$, the logarithmic convexity inequality (Lemma 5.6) dominates the preceding expression by

$$\left\| \sum_{T \in \mathcal{T}[\bar{S}_{t-1}]} \chi_T \right\|_{L^p_{k,M}(\mathbb{R}^n, \bar{S}_{t-1})} \leq \left( \frac{\delta_{t-1}}{\delta} \right)^{n} \sum_{S_{t-1} \in S_{t-1}} #\mathcal{T}[\bar{S}_{t-1}] .$$

Observe that, trivially, one has

$$\left\| \sum_{T \in \mathcal{T}[\bar{S}_{t-1}]} \chi_T \right\|_{L^p_{k,M}(\mathbb{R}^n, \bar{S}_{t-1})} \leq \left( \frac{\delta_{t-1}}{\delta} \right)^{n} \sum_{S_{t-1} \in S_{t-1}} #\mathcal{T}[\bar{S}_{t-1}] .$$

and, by Property 2 for the tube families $\{ T[\bar{S}_t] : \bar{S}_t \in \bar{S}_t \}$ for $t - 1 \leq i \leq n - 1$, it follows that

$$\left\| \sum_{T \in \mathcal{T}[\bar{S}_{t-1}]} \chi_T \right\|_{L^p_{k,M}(\mathbb{R}^n, \bar{S}_{t-1})} \leq \left( \frac{\delta_{t-1}}{\delta} \right)^{n} \left( \prod_{i=t-1}^{n-1} D_{i+\varepsilon_0} \right)^{\delta^n #\mathcal{T}} .$$
One may readily verify that
\[ D_{\ell-1}^e C(\bar{D}_{\ell}; \bar{\delta}_\ell) \cdot \left( \frac{\delta_{\ell-1}}{\delta} \prod_{i=\ell-1}^{n-1} D_{i+e}^1 \right)^{\Theta_{\ell-1}} = C(\bar{D}_{\ell-1}; \bar{\delta}_{\ell-1}) \]
and so, combining the above estimates,
\[ \left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{\mathcal{B}_{k,A}^m(\mathbb{R}^n)} \lesssim C(\bar{D}_{\ell-1}; \bar{\delta}_{\ell-1}) [\delta^m \# \mathcal{T}]^{1-\Theta_{\ell-1}} \sum_{T \in \mathcal{T}[S_{\ell-1}]} \chi_T \left\| \Theta_{\ell-1} \right\|_{\mathcal{E}_{k-1}^{\ell-1} \mathcal{B}_{k,A}^{p_{\ell-1}} (S_{\ell-1})}, \]
which is Property 1.

The final stage. If the algorithm has not stopped by the \( k \)th step, then it necessarily terminates at the \( k \)th step. Indeed, otherwise \( [S_m] \) would hold for \( \ell = k - 1 \) and families \( \mathcal{T}[S_{k-1}] \) of \( \delta_{k-1} \)-tubes which are tangent to some transverse complete intersection of dimension \( k - 1 \). By the vanishing property of the \( k \)-broad norms as described in Lemma 5, one would then have
\[ \left\| \sum_{T \subseteq \mathcal{T}[S_{k-1}]} \chi_T \right\|_{\mathcal{B}_{k,A}^{p_{k-1}} (B[S_{k-1}])} = 0, \]
which, by \( [15] \), would contradict the non-degeneracy hypothesis \( [14] \).

Suppose the recursive process terminates at step \( m \), so that \( m \geq k \). For each \( S_m \in \tilde{S}_{m,\text{tiny}} \) let \( \mathcal{O}[S_m] \) denote the final collection of cells output by \([\text{alg 1}]\) (that is, the collection denoted by \( \mathcal{O} \) in the notation of the previous subsection) when applied to estimate the broad norm \( \left\| \sum_{T \subseteq \mathcal{T}[S_m]} \chi_T \right\|_{\mathcal{B}_{k,A}^m (B[S_m])} \). By Properties I, II and III of \([\text{alg 1}]\) one has
\[ \left\| \sum_{T \subseteq \mathcal{T}[S_m]} \chi_T \right\|_{\mathcal{B}_{k,A}^m (B[S_m])} \lesssim \sum_{O \subseteq \mathcal{O}[S_m]} \left\| \sum_{T \subseteq \mathcal{T}[O]} \chi_T \right\|_{\mathcal{B}_{k,A}^m (B[S_m])} \]
for some \( A_{m-1} \sim A_m \) where the families \( \mathcal{T}[O] \) satisfy
\[ \sum_{O \subseteq \mathcal{O}[S_m]} \# \mathcal{T}[O] \lesssim D_{m-1}^{1+\varepsilon_1} \# \mathcal{T}[S_m] \] (51)
and
\[ \max_{O \subseteq \mathcal{O}[S_m]} \# \mathcal{T}[O] \lesssim D_{m-1}^{-(m-1)+\varepsilon_2} \# \mathcal{T}[S_m] \] (52)
for \( D_{m-1} \) a large and (in general) non-admissible parameter. Once again, by pigeonholing, one may pass to a subcollection of \( \tilde{S}_{m,\text{tiny}} \) and thereby assume that the \( D_{m-1} \) (and also the \( A_{m-1} \)) all share a common value.

If \( \mathcal{O} \) denotes the union of the \( \mathcal{O}[S_m] \) over all \( S_m \) belonging to subcollection of \( \tilde{S}_{m,\text{tiny}} \) described above, then \([\text{alg 2}]\) outputs the following inequality.

First key estimate.
\[ \left\| \sum_{T \subseteq \mathcal{T}} \chi_T \right\|_{\mathcal{B}_{k,A}^m (\mathbb{R}^n)} \lesssim C(\bar{D}_m; \bar{\delta}_m) [\delta^m \# \mathcal{T}]^{1-\Theta_m} \left( \sum_{O \subseteq \mathcal{O}} \left\| \sum_{T \subseteq \mathcal{T}[O]} \chi_T \right\|_{\mathcal{B}_{k,A}^m (\mathcal{O})} \right)^{\frac{p_m}{p_m}}. \]
8. Proof of Theorem 4.1

Henceforth, fix $T$ to be a direction-separated family of $\delta$-tubes in $\mathbb{R}^n$. Without loss of generality, we may assume that $T$ satisfies the non-degeneracy hypothesis \[\text{(4)}\]. The algorithms described in the previous section can be applied to this tube family, leading to the final decomposition of the broad norm described in the first key estimate. One therefore wishes to show, using the direction-separated hypothesis, that the quantity on the right-hand side of the first key estimate can be effectively bounded, provided that the exponents $p_k, \ldots, p_m$ are suitably chosen.

Since each $O \in \mathcal{O}$ is contained in a ball of radius at most $\delta^{1-\varepsilon_0}$, trivially one may bound

$$
\left\| \sum_{T \in T[O]} \chi_T \right\|_{BL_{k,A}^m(\mathbb{R}^n)}^{p_m} \leq \delta^n \left( \#T[O] \right)^{p_m}.
$$

Recalling that $\Theta_m(1 - \frac{1}{p_m}) = 1 - \frac{1}{p}$, this yields

$$
\left( \sum_{O \in \mathcal{O}} \sum_{T \in T[O]} \chi_T \right)^{p_m} \lesssim \left( \max_{O \in \mathcal{O}} \#T[O] \right)^{1 - \frac{1}{p}} \left( \delta^n \sum_{O \in \mathcal{O}} \#T[O] \right)^{\frac{p_m}{p^n}}.
$$

Now \[\text{(5)}\] and repeated application of Property 2 from \[\text{[alg 2]}\] imply

$$
\sum_{O \in \mathcal{O}} \#T[O] \lesssim \left( \prod_{i=m-1}^{n-1} D_i^{1+\varepsilon_0} \right) \#T.
$$

Combining this with the first key estimate and the definition of $C(\tilde{D}_m; \tilde{\delta}_m)$, one concludes that

$$
\left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{BL_{k,A}(\mathbb{R}^n)} \lesssim C(\tilde{D}; \tilde{\delta}) \left( \max_{O \in \mathcal{O}} \#T[O] \right)^{1 - \frac{1}{\delta}} \left( \delta^n \sum_{T \in \mathcal{T}} |T| \right)^{\frac{1}{\delta}}
$$

(53)

where, taking $\delta_{m-1} := \tilde{\delta}$, the constant takes the form

$$
C(\tilde{D}; \tilde{\delta}) := \prod_{i=m-1}^{n-1} \left( \frac{\delta_i}{\tilde{\delta}} \right)^{\Theta_i + 1 - \Theta_i} D_i^{\Theta_i + 1 - \frac{1}{\delta_i} + O(\varepsilon_0)}.
$$

In order to bound the maximum appearing on the right-hand side of \[\text{(53)}\], by \[\text{(62)}\] and repeated application of Property 3 of \[\text{[alg 2]}\], it follows that

$$
\max_{O \in \mathcal{O}} \#T[O] \lesssim \left( \prod_{i=m-1}^{\ell-1} D_i^{1+\varepsilon_0} \right) \max_{S_i \in \mathcal{S}_i} \#T[S_i]
$$

whenever $m \leq \ell \leq n$. Recall, for each tube family $T[S_i]$ produced by \[\text{[alg 2]}\] and each $\ell \leq i \leq n-1$ there exists a $\delta_i$-ball $B_{\delta_i} := B[S_i]$ such that every $\delta$-tube $T \in T[S_i]$ is tangent to $S_i$ in $B_{\delta_i}$; in particular,

$$
T \cap B_{\delta_i} \cap N_{\delta_i} S_i \neq \emptyset \quad \text{and} \quad T \cap 2B_{\delta_i} \subseteq N_{2\delta_i} S_i \quad \text{for} \ \ell \leq i \leq n-1.
$$

Here $S_i$ is a transverse complete intersection of dimension $i$ and $\deg S_i$ depends only on the admissible parameters $n, p$ and $\varepsilon$. Thus, Theorem 1.4 implies that

$$
\#T[S_i] \leq \# \left\{ T \in \mathcal{T} : |T \cap 2B_{\delta_i} \cap N_{2\delta_i} S_i| \geq 2\delta_i |T| \right\} \lesssim \delta^{-(n-1)} \prod_{i=\ell}^{n-1} \left( \frac{\delta_i}{\tilde{\delta}} \right)^{-1},
$$
where the first inequality follows from elementary geometric considerations. Combining these observations,

$$\max_{O \in \mathcal{O}} \# \mathcal{T}[O] \lesssim \left( \prod_{i=m-1}^{\ell-1} D_i^{-i+\varepsilon_i} \right) \delta^{-(n-1)} \prod_{i=\ell}^{n-1} \left( \frac{\delta_i}{\delta} \right)^{-1}.$$  

for all $m \leq \ell \leq n$. Finally, these $n - m + 1$ different estimates can be combined into a single inequality by taking a weighted geometric mean, yielding:

**Second key estimate.** Let $0 \leq \gamma_m, \ldots, \gamma_n \leq 1$ satisfy $\sum_{j=m}^{n} \gamma_j = 1$. Then

$$\max_{O \in \mathcal{O}} \# \mathcal{T}[O] \lesssim \left( \prod_{i=m-1}^{n-1} \left( \frac{\delta_i}{\delta} \right)^{-i} \sum_{j=m}^{i} \gamma_j D_i^{-i(1-\sum_{j=m}^{i} \gamma_j) + O(\varepsilon_i)} \right) \delta^{-(n-1)}.$$  

When $i = m - 1$ the $(\delta_i/\delta)^{-i} \sum_{j=m}^{i} \gamma_j$ factor is understood to be equal to 1.

Substituting the second key estimate into (53), one obtains

$$\left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{BL^k_{p,A}(\mathbb{R}^n)} \lesssim \left( \prod_{i=m-1}^{n-1} \left( \frac{\delta_i}{\delta} \right)^{X_i} D_i^{Y_i + O(\varepsilon_i)} \right) \delta^{-(n-1)\frac{1}{p}} \left( \sum_{T \in \mathcal{T}} |T| \right)^{\frac{1}{p}}$$  

where

$$X_i := \Theta_{i+1} - \Theta_i - \left( \sum_{j=m}^{i} \gamma_j \right) \left( 1 - \frac{1}{p} \right);$$  

$$Y_i := \Theta_{i+1} - \left( 1 + i \left( 1 - \sum_{j=m}^{i} \gamma_j \right) \right) \left( 1 - \frac{1}{p} \right).$$  

One now chooses the various exponents so that $X_i, Y_i = 0$ for all $m \leq i \leq n - 1$ and $Y_{m-1} = 0$. This ensures that the $(\delta_i/\delta)^{X_i}$ and $D_i^{Y_i}$ factors in the above expression are admissible but does not allow one to control the $D_i^{O(\varepsilon_i)}$ factors, which may still be non-admissible. To deal with the $D_i^{O(\varepsilon_i)}$ one may perturb the $p$ exponent which results under the conditions $X_i, Y_i = 0$, so that $Y_i$ becomes negative, and then choose $\varepsilon_i$ sufficiently small depending on the choice of perturbation. This yields an open range of $k$-broad estimates, which can then be trivially extended to a closed range via interpolation through logarithmic convexity (the interpolation argument relies on the fact that one is permitted an $\delta^{-\varepsilon}$-loss in the constants in the $k$-broad inequalities).

The condition $X_i = 0$ is equivalent to

$$\left( 1 - \frac{1}{p_{i+1}} \right)^{-1} - \left( 1 - \frac{1}{p_i} \right)^{-1} = \sum_{j=m}^{i} \gamma_j$$  

whilst the condition $Y_{i-1} = 0$ is equivalent to

$$\left( 1 - \frac{1}{p_i} \right)^{-1} = i - (i - 1) \sum_{j=m}^{i-1} \gamma_j.$$
Choose \( p_m := \frac{m}{m-1} \) so that (55) holds in the \( i = m \) case. The remaining \( p_i \) are then defined in terms of the \( \gamma_j \) by the equation

\[
(1 - \frac{1}{p_i})^{-1} = m + \sum_{j=m}^{i-1} (i-j)\gamma_j
\]

so that each of the \( n - m \) constraints in (54) is met.

It remains to solve for the \( n - m + 1 \) variables \( \gamma_m, \ldots, \gamma_n \). By comparing the right-hand sides of (55) and (56), it follows that

\[
\sum_{j=m}^{i-1} (2i-j-1)\gamma_j = i - m \quad \text{for } m + 1 \leq i \leq n.
\]

To solve this linear system, let \( \kappa_i \) denote the left-hand side of (57) and observe that

\[
\kappa_{i+1} + \kappa_i - 2\kappa_i = (i+1)\gamma_i - (i-2)\gamma_{i-1} \quad \text{for } m + 1 \leq i \leq n - 1,
\]

where \( \kappa_m := 0 \). On the other hand, by considering the right-hand side of (57), it is clear that \( \kappa_{i+1} + \kappa_i - 2\kappa_i = 0 \). Combining these observations gives a recursive relation

\[
\gamma_m := \frac{1}{m + 1}, \quad \gamma_i = \left( \frac{i-2}{i+1} \right)\gamma_{i-1} \quad \text{for } m + 1 \leq i \leq n
\]

and from this one deduces that

\[
\gamma_j = \frac{1}{m + 1} \prod_{i=m}^{j-1} \frac{i-1}{i+2} = \frac{(m-1)m}{(j-1)j(j+1)} \quad \text{for } m \leq j \leq n - 1.
\]

It remains to check that these parameter values give the correct value of \( p_n \), corresponding to the exponent featured in Theorem 4.1. It follows from (55) that

\[
\left(1 - \frac{1}{p_n}\right)^{-1} = n - (n-1)(m-1)m \sum_{j=m}^{n-1} \frac{1}{(j-1)j(j+1)} = n - \frac{(n-1)n - (m-1)m}{2n}.
\]

This is smallest when \( m = k \), which directly yields the desired range of \( p \), as stated in Theorem 4.1, completing the proof.

9. Remarks on the numerology and related results

In this section we discuss the relationship between the main result of this paper and the existing literature on the Kakeya set conjecture. The first step is to obtain a more explicit range of exponents for Theorem 1.2, which is treated in the following subsection. Later, we also discuss applications of the method of this article to certain variants of the Kakeya maximal problem.

9.1. Numerology. Recall that the range of exponents in Theorem 1.2 is given by

\[
p \geq 1 + 1 \min_{2 \leq k \leq n} \left\{ \frac{2n}{n(n-1)+k(k-1)}, \frac{1}{n-k+1} \right\},
\]

as claimed in the introduction, this guarantees that Conjecture 1.1 holds in the range

\[
p \geq 1 + \frac{1}{2 - \sqrt{2}} \frac{1}{n-1}.
\]
In fact, in many dimensions a somewhat better bound is obtained. To see this, allowing \( k \) to be non-integer for a moment, one finds that the minimum value in (58) is attained when \( k = k_1 \) where \( k_1 = k_1(n) \) is chosen so that

\[
\frac{2n}{n(n-1) + k_1(k_1 - 1)} = \frac{1}{n - k_1 + 1}.
\]

Solving the quadratic, one deduces that

\[
k_1 = (\sqrt{2} - 1)n + \frac{1}{2} + \sqrt{2n} \left( (1 + \frac{1}{n} + \frac{1}{8n^2})^{1/2} - 1 \right)
\]

\[
\leq (\sqrt{2} - 1)n + \frac{1}{2} + \frac{1}{\sqrt{2}} + \frac{1}{8\sqrt{2}n},
\]

where the upper bound follows by Bernoulli’s inequality. Let \( \tilde{k}_1 \) denote the expression appearing on the last line of the above display. Since the sequence \((\sqrt{2} - 1)n\) is equidistributed modulo 1, for any \( \varepsilon > 0 \) there exist infinitely many values of \( n \) for which the interval \([\tilde{k}_1, \tilde{k}_1 + \varepsilon]\) contains an integer. For any such value of \( n \) it follows that Conjecture 1.1 is true in the range

\[
p \geq 1 + \frac{1}{(2 - \sqrt{2})n + \frac{1}{2} - \frac{1}{\sqrt{2}} - \frac{1}{8\sqrt{2}n}} + \varepsilon.
\]

On the other hand, considering the worst case scenario, when \( k \) is not close to an integer, we can at least find an integer in \([k_0, k_0 + 1]\), with \( k_0 = k_0(n) \) chosen so that

\[
\frac{2n}{n(n-1) + k_0(k_0 - 1)} = \frac{1}{n - (k_0 + 1) + 1}.
\]

Calculating \( k_0 \) and bounding from above using Bernoulli’s inequality as before, we find that, in any dimension, Conjecture 1.1 is true in the range

\[
p \geq 1 + \frac{1}{(2 - \sqrt{2})n - \frac{1}{2} - \frac{1}{8\sqrt{2}n}}.
\]

This range is always larger than the one stated in (59).

9.2. **Implications for the Kakeya set conjecture.** As mentioned in the introduction, a maximal estimate of the form \((K_p)^{1/p'}\) implies that the Hausdorff dimension of any Kakeya set must be greater than or equal to \(p'\), where \(1/p + 1/p' = 1\). It is instructive to compare the Hausdorff dimension bounds obtained from Theorem 1.2 with the current best known high dimensional results on the Kakeya set conjecture due to Katz and Tao [27]. In particular, in [27] it was shown that Kakeya sets in \(\mathbb{R}^n\) have Hausdorff dimension greater than or equal to \((2 - \sqrt{2})(n - 4) + 3\). Considering the best case scenario from the previous section, we are able to obtain the following improvement.

**Corollary 9.1.** For every \( \varepsilon > 0 \) there exists an infinite sequence of dimensions \( n \) such that every Kakeya set \( K \subseteq \mathbb{R}^n \) satisfies

\[
\dim_H K \geq (2 - \sqrt{2})n + \frac{3}{2} - \frac{1}{\sqrt{2}} - \varepsilon.
\]

4This is an improved range over what can be obtained directly from the maximal estimate in [27]; an even larger bound for the Minkowski dimension is obtained in [27] for dimensions \( n \geq 24 \).
Provided $\varepsilon > 0$ is sufficiently small, this bound is stronger than that obtained by Katz–Tao [27]. On the other hand, the Hausdorff dimension bound provided by Theorem 1.2 is also weaker than the result [27] for infinitely many dimensions. In our worst case scenario, arguing as in the previous subsection, given any $\varepsilon > 0$ we can find infinitely many dimensions $n$ for which our results do not provide a better bound than

$$\dim_H K \geq (2 - \sqrt{2})n + 1 + \varepsilon.$$ 

Provided $\varepsilon > 0$ is sufficiently small, this is strictly worse than the Katz–Tao Hausdorff dimension estimate. See Figure 5 for the state-of-the-art in lower dimensions. It is perhaps interesting that the polynomial partitioning approach of this article yields the same $(2 - \sqrt{2})n + O(1)$ numerology as the (completely different) sum-difference approach employed by Katz and Tao [27].

9.3. Further variants of the Kakeya problem. It is an interesting problem to determine what can be said when the direction-separation hypothesis in Conjecture 1.1 is weakened; indeed, results of this kind have greatly influenced the current understanding of the Kakeya conjecture (see, for instance, [38]). One classical theorem in this direction is due to Wolff [41] and considers families of tubes which satisfy the following hypothesis.

**Definition 9.2.** Let $N \geq 1$ and $T$ be a family of $\delta$-tubes in $\mathbb{R}^n$. We say that $T$ satisfies the $(N)$-linear **Wolff axiom** if

$$\# \{T \in T : T \subseteq E\} \leq N\delta^{-n-1}|E|$$

whenever $E \subseteq \mathbb{R}^n$ is a rectangular box of arbitrary dimensions.

In [41], Wolff showed that the maximal inequality

$$\left\| \sum_{T \in T} \chi_T \right\|_{L^p(\mathbb{R}^n)} \leq C_{n,\varepsilon} N^{1-1/p} \delta^{-\frac{(n-1)}{2} - \varepsilon} \left( \sum_{T \in T} |T| \right)^{1/p}$$

(60)

holds for the restricted range $p \geq \frac{n+2}{n}$ whenever $T$ satisfies the $(N)$-linear Wolff axiom. Furthermore, it is not difficult to see that any direction-separated $T$ satisfies

---

[5] Strictly speaking, Wolff’s theorem [41] holds under a slightly less restrictive condition referred to simply as the Wolff axiom. See [22] for a comparison of these conditions.
the \((N)\)-linear Wolff axiom for some \(N \sim 1\) and so his result provided similar progress for Conjecture 1.1.

Interestingly, there exist examples of tube families \(T\) in dimensions \(n \geq 4\) that satisfy the \((N)\)-linear Wolff axiom with \(N \sim 1\), but for which (60) fails to hold for the whole range \(p > \frac{n}{n-1}\); see [37]. In particular, when \(n = 4\) one may construct such \(T\) for which (60) is only valid in Wolff’s range \(p \geq 3/2\). Examples of this kind are not direction-separated and therefore do not provide counterexamples to Conjecture 1.1.

To go beyond \(p \geq 3/2\) in four dimensions, Guth and Zahl [22] considered families of tubes which satisfy a more restrictive version of the \((N)\)-linear Wolff axiom.

**Definition 9.3.** We say that \(N\) of tubes which satisfy a more restrictive version of the \((\lambda)\)-linear Wolff axiom whenever \(\lambda \geq \delta\) and \(E \subseteq \mathbb{R}^n\) is a semialgebraic set of complexity at most \(D\).

In this language, Theorem 1.3 states that for all \(D \in \mathbb{N}\) and all \(\epsilon > 0\) there is a constant \(C(D, \epsilon, n)\) such that any direction-separated family \(T\) satisfies the \((D, N)\)-polynomial Wolff axiom with \(N = C(D, \epsilon, n)\delta^{-\epsilon}\). Thus, the following conjecture of Guth and Zahl [22] Conjecture 1.1 is stronger than the Kakeya maximal conjecture.

**Conjecture 9.4 (Guth–Zahl [22]).** Let \(p \geq \frac{n - 1}{n-4}.\) Then, for all \(\epsilon > 0\), there is a complexity \(D = D_{\epsilon, n} \in \mathbb{N}\) and a constant \(C_{\epsilon, n} > 0\) such that

\[
\left\| \sum_{T \in \mathcal{T}} \chi_T \right\|_{L^p(\mathbb{R}^n)} \leq C_{\epsilon, n}N^{1-1/p} \delta^{-(n-1-n/p)-\epsilon} \left( \sum_{T \in \mathcal{T}} |T| \right)^{1/p}
\]

whenever \(0 < \delta < 1\), \(N \geq 1\) and \(\mathcal{T}\) satisfies the \((D, N)\)-polynomial Wolff axiom.

It is easy to adapt C´ordoba’s \(L^2\)-argument [11] to prove Conjecture 9.4 for \(n = 2\). Guth and Zahl [22] showed that in four dimensions, under the polynomial Wolff axioms, the \(p \geq 3/2\) bound can be improved to \(p \geq 121/81\)\(^7\). Later, Katz and Zahl [29] obtained a slight improvement over the Wolff bound \(p \geq 5/3\) for Conjecture 9.4 in three dimensions. In all other dimensions the Wolff bound \(p \geq \frac{2n}{n-2}\) provides the previous best known result under the polynomial Wolff axioms alone. By carrying out the analysis of this paper, but only using the polynomial Wolff axiom rather than the nested estimates from Theorem 1.3, one obtains the following range of estimates.

**Theorem 9.5.** Conjecture 9.4 is true in the range

\[
p \geq 1 + \min_{2 \leq k \leq n} \max \left\{ \left( \frac{n}{n-1} \right)^{n-k}, \frac{n-1}{n-k+1} \right\} \frac{1}{n-1}.
\]

(61)

The above range of exponents is larger than Wolff’s when \(n = 5\) or \(n \geq 7\). To see this, note that for any \(0 < r < 1\) there exists some integer \(2 \leq k \leq n\) satisfying \(k \in [r(n-1)+1, r(n-1)+2]\). Writing the endpoint in (61) as \(1 + \frac{\alpha_n}{n-1}\), it follows that

\[
\alpha_n < \inf_{0<r<1} \max \left\{ \left( 1 + \frac{1}{n-1} \right)^{(n-1)(1-r)}, \frac{1}{1-r} \right\} \leq \Omega^{-1} = 1.763.\]

\(^6\)Strictly speaking, the conjecture of [22] is slightly weaker than Conjecture 9.4 in some regards and stronger in others.

\(^7\)The original paper [22] claimed the range \(p \geq 85/57\) but contained an arithmetic error, as highlighted in [29].
Here the omega constant $\Omega \in (1/2, 1)$ is the solution to $e^\Omega = \Omega - 1$. In particular, Theorem 9.5 implies that Conjecture 9.4 is true in the range $p \geq 1 + \Omega - 1\frac{n}{n-1}$, yielding an improvement over Wolff’s bound when $n \geq 9$. Calculating the precise value of $p_n$ for lower $n$, we find that Theorem 9.5 also improves the state-of-the-art for Conjecture 9.4 in dimensions $n = 5, 7, 8$; see Figure 6 for some explicit values for $(61)$.

\begin{figure}[h]
\centering
\begin{tabular}{|c|c|c|c|c|}
\hline
$n$ & $p \geq$ & $n$ & $p \geq$ \\
\hline
2 & 2 & 9 & $1 + 9^4/8^5$ & Theorem 9.5 \\
3 & $5/3 - \varepsilon$ & 10 & $1 + 10^5/9^6$ & Theorem 9.5 \\
4 & $121/81$ & 11 & $7/6$ & Theorem 9.5 \\
5 & $1 + 5^2/4^3$ & 12 & $1 + 12^6/11^7$ & Theorem 9.5 \\
6 & $4/3$ & 13 & $8/7$ & Theorem 9.5 \\
7 & $1 + 7^3/6^4$ & 14 & $1 + 14^7/13^8$ & Theorem 9.5 \\
8 & $1 + 8^4/7^5$ & 15 & $1 + 15^8/14^9$ & Theorem 9.5 \\

\section*{Appendix A. Tools from real algebraic geometry}

For the reader’s convenience, here we recall the definitions and results from real algebraic geometry that play a role in our arguments in Section 3.

\begin{itemize}
\item \textbf{Wongkew’s theorem.} We make considerable use of the following theorem of Wongkew \cite{43} (see also \cite{18, 45}), which bounds the volume of neighbourhoods of algebraic varieties.

\begin{theorem}[Wongkew \cite{43}]
Suppose $Z$ is an $m$-dimensional variety in $\mathbb{R}^n$ with $\deg Z \leq d$. For any $0 < \rho \leq \lambda$ and $\lambda$-ball $B_\lambda$ the neighbourhood $N_\rho(Z \cap B_\lambda)$ can be covered by $O_d((\lambda/\rho)^m)$ balls of radius $\rho$.
\end{theorem}

\textbf{The Tarski–Seidenberg projection theorem.} A fundamental result in the theory of semialgebraic sets is the Tarski–Seidenberg projection theorem, which is also referred to as “quantifier elimination”. A useful reference for this material is \cite{2}.

\begin{theorem}[Tarski–Seidenberg]
Let $\Pi$ be the orthogonal projection of $\mathbb{R}^n$ into its first $n - 1$ coordinates. Then for every $E \geq 1$, there is a constant $C(n, E) > 0$ so that, for every semialgebraic $S \subset \mathbb{R}^n$ of complexity at most $E$, the projection $\Pi(S)$ has complexity at most $C(n, E)$.
\end{theorem}

We repeatedly use Theorem A.2 to form semialgebraic sections of semialgebraic sets.

\begin{corollary}
Let $S \subset \mathbb{R}^{2n}$ be a compact semialgebraic set of complexity at most $E$. Let $\Pi$ be the orthogonal projection into the final $n$ coordinates $(a, d) \mapsto d$. Then there is a constant $C(n, E) > 0$, depending only on $n$ and $E$, and a semialgebraic set $Z$, of complexity at most $C(n, E)$, so that

$Z \subset S, \quad \Pi(Z) = \Pi(S),$
\end{corollary}
and so that for each \( \mathbf{d} \), there is at most one \( \mathbf{a} \) with \((\mathbf{a}, \mathbf{d}) \in \mathbb{Z}\).

This is Lemma 2.2 from \[23\]. It is a direct consequence of Theorem A.2, as discussed in \[25\].

**Gromov’s algebraic lemma.** The final key tool is the existence of useful parameterisations of semialgebraic sets, as guaranteed by the following lemma.

**Lemma A.4** (Gromov). For all integers \( E, n, r \geq 1 \), there exists \( M(E, n, r) < \infty \) with the following properties. For any compact semialgebraic set \( A \subset [0, 1]^n \) of dimension \( m \) and complexity at most \( E \), there exists an integer \( N \leq M(E, n, r) \) and \( C^r \) maps \( \phi_1, \ldots, \phi_N : [0, 1]^m \to [0, 1]^n \) such that

\[
\bigcup_{j=1}^N \phi_j([0,1]^m) = A \quad \text{and} \quad \|\phi_j\|_{C^r} := \max_{|\alpha| \leq r} \|\partial^{\alpha} \phi_j\|_{\infty} \leq 1.
\]

This result was originally stated by Gromov. Detailed proofs were later given by Pila and Wilkie \[33\] and Burguet \[8\].
