Influencing the orientation of Jahn-Teller axes in butterfly-like Mn\textsuperscript{III}\textsubscript{4} clusters

Ross McLellan,\textsuperscript{[a]} Maria A. Palacios,\textsuperscript{[b]} Euan K. Brechin\textsuperscript{[b]} and Scott J. Dalgarno\textsuperscript{[a]}

A bis-phenolate that has structural similarities to both calix[4]arene and the oxcalix[n]arenes provides access to a ‘butterfly’-like Mn\textsubscript{4} cluster in which all metals are in the oxidation state +3. Specific properties of this ligand, in comparison to others in the literature, offer a route to influencing the orientation of the Jahn-Teller axes within this cluster motif, which possesses a rare oxidation state arrangement.

Methylene-bridged calix[n]arenes are cyclic polyphenols that have emerged as excellent platforms for the synthesis of new polynuclear transition and lanthanide metal clusters (TM and Ln respectively).\textsuperscript{[1,2]} We have explored this chemistry extensively with p-Bu-calix[4]arene / calix[4]arene (TBC[4] / C[4]) in particular and have reported a range of novel cluster motifs including: a) [Mn\textsubscript{10}Mn\textsubscript{2}TBC[4]\textsubscript{2}]\textsuperscript{2+} Single-Molecule Magnets (SMMs, Fig. 1);\textsuperscript{[3b,c]} b) [Cu\textsubscript{3}TBC[4]\textsubscript{3}]\textsuperscript{2+} clusters\textsuperscript{[3d]} that are versatile anion binding materials; c) [Mn\textsubscript{6}Ln\textsubscript{6}C[4]\textsubscript{4}]\textsuperscript{4+} clusters that are magnetic refrigerants or SMMs depending on the lanthanide employed;\textsuperscript{[4a-f]} d) [Fe\textsubscript{9}Ln\textsubscript{8}TBC[4]\textsubscript{2}]\textsuperscript{2+} clusters\textsuperscript{[4g-h]} and e) octahedral [Ln\textsubscript{6}TBC[4]\textsubscript{2}]\textsuperscript{2+} clusters.\textsuperscript{[4i]} This study has allowed us to establish a set of metal-ion binding rules for the general C[4] framework, and perhaps the most important feature of this is that the polyphenolic pocket shows strong affinity for Mn\textsuperscript{3+} ions in competition experiments.

The metallic skeleton in the [Mn\textsubscript{10}Mn\textsubscript{2}TBC[4]\textsubscript{2}]\textsuperscript{2+} SMMs mentioned above describes a planar diamond or butterfly-like topology in which the wing-tip manganese ions (within the C[4] cavity) are in the oxidation state +3, and the body manganese ions are in the oxidation state +2 (Fig. 1). These ions are linked via two µ-OH ions located in the center of the diamond forming a [Mn\textsubscript{10}Mn\textsubscript{2}OH\textsubscript{2}]\textsuperscript{5+} core. The four positions around the equatorial plane of each wing-tip Mn\textsuperscript{3+} ion are occupied by the oxygen atoms of a TBC[4] support, and in each case two of these µ-bridge to the central Mn\textsuperscript{3+} ions. The remaining positions around all of the Mn\textsubscript{5}Mn\textsubscript{10} ions are occupied by ligated DMF molecules and the Jahn-Teller axes of the cavity-bound (and distorted octahedral) Mn\textsuperscript{3+} ions are defined by the O(DMF)-Mn-O(µ-OH) vector.

A search of the Cambridge Structural Database for clusters with a general Mn\textsubscript{10}O\textsubscript{2} core (Fig. 2A) with no specific oxidation state distributions returns a total of 66 entries.\textsuperscript{[5]} Analysis revealed a number of interesting trends. The first is that the vast majority of these have the opposite oxidation state distribution to that found in the [Mn\textsubscript{10}Mn\textsubscript{2}TBC[4]\textsubscript{2}] SMM, i.e. the wing-tip and body ions of the butterfly are Mn\textsuperscript{10} and Mn\textsuperscript{3+}, respectively.\textsuperscript{[6,7]} Six clusters have an arrangement in which wing-tip and body Mn ions are all in the oxidation state +3, five of which are formed from reactions with ligands containing salicylideneamino moieties (see Figure 2B).\textsuperscript{[5-7]}

Figure 1. [Mn\textsubscript{10}Mn\textsubscript{2}TBC[4]\textsubscript{2}] Single-Molecule Magnet showing a) the butterfly-like cluster motif, b) bridging nature of the µ-OH (H atoms not shown) and TBC[4] anions, c) ligated DMF occupying the TBC[4] cavities and d) the Jahn-Teller axes defined by the O(DMF)-Mn-O(µ-OH) vector indicated with arrows.\textsuperscript{[3c,d]}

Figure 2. A) General Mn\textsubscript{10}O\textsubscript{2} butterfly fragment used for the CSD analysis. B) Examples of salicylideneamino containing ligands that afford butterfly-like clusters in which all Mn ions are in oxidation state +3.\textsuperscript{[5-7]} Common orientation of Jahn-Teller axes in ligands containing adjacent phenol and methanol moieties.\textsuperscript{[R]}

The final trend we observed is that, within our search for the general Mn\textsubscript{10}O\textsubscript{2} fragment / core, ligands containing phenol and ortho-methanol moieties bind Mn\textsuperscript{3+} ions with the Jahn-Teller axes oriented orthogonal to the near planar ligand fragment (Fig. 2C).\textsuperscript{[8]} We recently began to investigate TM and

Ln cluster formation with bis(5-tert-butyl-2-hydroxy-3-hydroxy-methylphenyl)methane (HL1, Fig. 3A) as it bears a striking similarity to calix[n]arenes and oxacalix[n]arenes, and would thus provide useful data for structural comparison to related building blocks. We have reported the formation of a family of near-linear LnIII trimers as well as a large CoII cluster using this ligand as a support. The latter involved in situ generation of carbonate which was found to play a pivotal structural role in cluster formation. In both cases L1 displayed calixarene character and accommodated varying degrees of deprotonation. Given the results arising from our CSD search we anticipated that it would be possible to a) bind two MnIII ions with this ligand, b) form a butterfly-like cluster and c) therefore influence the magnetic properties of the resulting assembly via the curvature associated with HL1. The second assumption was based on the remaining MnIII4 butterfly-like cluster [MnIII4(µ3-O)(µ2-OMe)3(µ2-OMe)2(MeOH)2] (1: AcVn = acetone-divanillin aldol) found in our CSD search (Fig. 3B). This cluster arises from an in situ MnIII-promoted double-aldol reaction between vanillin and acetone. Notably this di-vanillin ligand represents two halves of HL1 that are linked at the methanol functionality by an additional carbon atom bridge (compare Fig. 3A and 3C). Analysis of the cluster shows that the Jahn-Teller axes lie orthogonal to the phenol / methanol fragment planes in the acetone-di-vanillin ligand as one would predict.

Reaction of HL1, manganese (II) nitrate and base in methanol afforded dark green single crystals that were found to be of formula [MnIII4(L1)x(µ-OMe)4(µ2-OMe)3(MeOH)2]·2MeOH (2-2MeOH, Fig. 4). The crystals were found to be of triclinic symmetry and the asymmetric unit comprises one half of the expected tetranuclear butterfly-like cluster and a methanol of crystallization. The two crystallographically unique MnIII ions (Mn1 and Mn2, Fig. 4) are coordinated to a fully deprotonated L1 tetra-anion, one µ-OMe− (O7) and one µ2-OMe− (O5). The coordination sphere of Mn1 is completed by a ligated MeOH (O6) and symmetry equivalent (s.e.) µ2-OMe− (O5). Similarly the coordination sphere of Mn2 is completed by a ligated MeOH (O8) and a s.e. methoxide arm of the L1 tetra-anion (O4̅). Given the orientation of the phenol / methanol fragments in HL1, the orientation of the Jahn-Teller axes of Mn1 and Mn2 has been influenced and these lie perpendicular to each other as expected; as a result the two crystallographically unique axes are defined by the O6(MeOH)-Mn1-OS(µ2-OMe−) and O8(MeOH)-Mn2-OS(µ2-OMe−) vectors (Fig. 4).

Examination of the extended structure of 2 shows that the molecules assemble as H-bonded chains along the b axis within layers (Fig. S1), and this occurs with two crystallographically unique H-bonding interactions; one is found between the ligated MeOH on Mn2 and the MeOH of crystallization (O8−O9 distance of 2.578 Å), whilst the other is between the MeOH of crystallization and a s.e. methoxy arm of an L1 tetra-anion (O9−O2̅ distance of 2.680 Å). The closest intermolecular metal-metal distance is found to be 6.715 Å along the b axis, with other distances being significantly greater, thereby indicating that the clusters are well separated by the bis-phenolate ligand supports. The extended packing mimics that found in the aforementioned [MnIII4MnIII2(TBC[4]3)] SMMs (Figures S1-S3),[10b-d] and also that of the di-vanillin ligand supported cluster 1.[11]
3.13 and 5.34 Å respectively (Fig. 3B). Similar analysis of the polymeric core in 2 reveals Mn1-Mn1**, Mn1-Mn2, Mn2-Mn1** and Mn2-Mn2** distances of 3.18, 3.16, 3.10 and 5.39 Å (Fig. 4). Comparison between Figures 3B and 4 shows a marked difference in Jahn-Teller orientation between 1 and 2, a feature that is a direct result of the arrangement of the phenol / methanol fragments in the L1 ligands, and one that has important consequences for the resultant magnetic behaviour. Direct current magnetic susceptibility studies were performed on polycrystalline samples of 2 in the T = 5–300 K range in an applied field, H = 0.1 T. The results are plotted as the χμT product versus T in Figure 5. The χμT value of −14 cm³ K mol⁻¹ at 300 K is above the spin-only (g = 2.0) value of 12 cm³ K mol⁻¹ expected for four non-interacting high-spin MnIII (3d⁷) ions. The value increases constantly with decreasing temperature reaching a maximum value of ~28 cm³ K mol⁻¹ at 20 K, below which it decreases to a value of ~16 cm³ K mol⁻¹ at 5 K. This behaviour is indicative of the presence of ferromagnetic exchange between neighbouring metal ions, with the low temperature decline being due to intermolecular AF interactions and/or zero-field splitting (zfs) effects. The experimental data can be fitted to the isotropic spin-Hamiltonian (1), by use of the Levenberg–Marquardt algorithm:  

\[
\hat{H}_{iso} = -2 \sum_{i,j>i} J_{ij} \hat{S}_i \cdot \hat{S}_j + \mu_B H g \sum_i \hat{S}_i \tag{1}
\]

where \(i, j\) are indices running through the constituent single ions, \(J\) is the isotropic exchange parameter, \(\hat{S}\) is a spin operator, \(\mu_B\) is the Bohr magneton, \(g = 2.0\) is the \(g\)-factor of MnIII and \(H\) is the applied magnetic field. We have used the model in the inset of Figure 5, which includes two different exchange interactions. We have not included the T < 20 K data to avoid the use of additional [and correlated] intermolecular interactions and zfs parameters. This affords \(J_{1} = +8.64\) cm⁻¹ and \(J_{2} = + 1.34\) cm⁻¹ with the resulting \(S = 8\) ground state being separated by ~11 cm⁻¹ from the first (\(S = 7\)) excited state (Figure S4). A Cure-Weiss fit of the 1/χμT versus T data affords \(\theta = +23\) K. The nature and magnitude of the nearest neighbour interactions are consistent with a recently published magnetostuctural correlation (MSC) for alkoide-bridged MnIII dimers.\(^{13}\) Magnetisation data (Figure S5) collected in the \(T = 2-6\) K and \(H = 3 – 7\) T temperature and field ranges can be fitted by assuming only the ground spin-state is thermally populated under these experimental conditions. We employed anisotropic spin-Hamiltonian (2) that takes into account spin-variables relevant to the \(S = 8\) ground spin-state only.

\[
\hat{H}_{aniso} = D_S \left( \frac{1}{3} \hat{S}_z^2 - (S + 1) \hat{S}_z \right) + \mu_B H g_S \hat{S} \tag{2}
\]

where \(D\) and \(g = 2\) are the uniaxial anisotropy parameter and \(g\)-value of the \(S = 8\) ground spin-state. Spin-Hamiltonian (2) was fitted to the experimental data by use of the simplex algorithm,\(^{14}\) to give the best-fit parameter \(D_{(S=8)} = -0.37\) cm⁻¹.

In conclusion we have shown that it is possible to influence the orientation of MnIII ion Jahn-Teller axes in target cluster formation by ligand design, through careful control over substituent positioning. Control over the relative positions of JT axes in neighbouring MnIII ions has been shown recently to be crucial in determining the nature and magnitude of the magnetic exchange interaction. This will inform future ligand design and cluster formation with these and other calixarene analogue ligands. These results will be reported in due course.

Experimental Section

\(\text{H}_2\text{L}1\) was prepared according to literature procedures.\(^{15}\)

**Synthesis of 2-MeOH:** \(\text{H}_2\text{L}1\) (1g, 2.69 mmol) and Mn(NO₃)₂·4H₂O (1.35g, 5.38 mmol) were stirred in a mixture of dmf (10 mL) and MeOH (40 mL) for 10 minutes. NaN₃ (0.64 g, 16.14 mmol) in MeOH (50mL) was added and the dark green solution stirred for a further two hours. A dark green precipitate was collected by filtration and recrystallized from hot methanol, affording 2-MeOH in modest yield (34%). Elemental analysis (%) calculated for 1, \(\text{C}_{39}\text{H}_{32}\text{O}_{18}\text{Mn}_{18}\): C, 52.83%; H, 7.28%. Found: C, 52.53%; H, 7.49 %. [5] There are other related butterfly-like complexes in the literature in which all metal ions are in the oxidation state +3. These have not been included our discussion as they contain a markedly different core of bridging atoms / anions relative to the MnO$_4^-$ targeted in this study. For example see: J. B. Vincent, C. Christmas, H.-R. Chang, Q. Li, P. D. W. Boyd, J. C. Huffman, D. N. Hendrickson, G. Christou, *J. Am. Chem. Soc.* **1989**, *111*, 2066.

[12] Oxidation states were confirmed by both inspection and bond-valence sum calculations.
