FANO VARIETIES WITH MANY SELFMAPS

IVAN CHELTSOV

Abstract. We study global log canonical thresholds on anticanonically embedded quasismooth weighted Fano threefold hypersurfaces having terminal quotient singularities to prove the existence of a Kähler–Einstein metric on most of them, and to produce examples of Fano varieties with infinite discrete groups of birational automorphisms.

1. Introduction.

Let $X$ be a Fano variety of dimension $n$ that has at most log terminal singularities.

Definition 1.1. The global log canonical threshold of the variety $X$ is the number

$$\text{lct}(X) = \sup \left\{ \lambda \in \mathbb{Q} \mid \text{the log pair} \ (X, \lambda H) \text{ has log canonical singularities for every effective } \mathbb{Q}-\text{divisor} \ H \text{ such that} \ H \equiv -K_X \right\} \geq 0.$$ 

It follows from [13], [11], [6] that the Fano variety $X$ has an orbifold Kähler–Einstein metric in the case when $X$ has quotient singularities and the inequality $\text{lct}(X) > n/(n + 1)$ holds.

Example 1.2. Let $X$ be a general hypersurface in $\mathbb{P}(1^4,3)$ of degree 6. Then $\text{lct}(X) = 1$ by [12].

Quasismooth anticanonically embedded weighted Fano threefold hypersurfaces with terminal singularities are studied extensively in [5], [3], [2], [4]. In this paper we prove the following result.

Theorem 1.3. Let $X$ be a general quasismooth hypersurface in $\mathbb{P}(1,a_1,...,a_4)$ of degree $\sum_{i=1}^4 a_i$ having at most terminal singularities such that $-K_X^3 \leq 1$. Then $\text{lct}(X) = 1$.

The proof of Theorem 1.3 is algebro-geometric, but Theorem 1.3 implies the following result.

Corollary 1.4. With the assumptions of Theorem 1.3 the variety $X$ has a Kähler–Einstein metric.

It follows from [5], [12] that Theorem 1.3 also implies the following result (see Theorem 6.5).

Corollary 1.5. Let $X_1,...,X_r$ be varieties that satisfy all hypotheses of Theorem 1.3. Then

$$\text{Bir} \left( X_1 \times \cdots \times X_r \right) = \left\langle \prod_{i=1}^r \text{Bir}(X_i), \ \text{Aut} \left( X_1 \times \cdots \times X_r \right) \right\rangle,$$

the variety $X_1 \times \cdots \times X_r$ is non-rational, and for any dominant map $\rho: X_1 \times \cdots \times X_r \to Y$ whose general fiber is rationally connected, there is a commutative diagram

$$\begin{array}{ccc}
X_1 \times \cdots \times X_r & \xrightarrow{\sigma} & X_1 \times \cdots \times X_r \\
\downarrow \pi & & \downarrow \rho \\
X_{i_1} \times \cdots \times X_{i_k} & \xrightarrow{\xi} & Y,
\end{array}$$

where $\xi$ and $\sigma$ are birational maps, and $\pi$ is a projection for some $\{i_1,\ldots,i_k\} \subset \{1,\ldots,r\}$.

Unlike those of dimension three, no Fano varieties of dimension four or higher having infinite groups of birational automorphisms whose birational automorphisms are well understood have been known so far. However, we can now easily obtain the following example.

Example 1.6. Let $X$ be a general hypersurface in $\mathbb{P}(1,1,4,5,10)$ of degree 20. Then it immediately follows from [5], [3] and Corollary 1.3 that there is an exact sequence of groups

$$1 \to \prod_{i=1}^m \left( \mathbb{Z}_2 \ast \mathbb{Z}_2 \right) \to \text{Bir} \left( X \times \cdots \times X \right) \to S_m \to 1,$$

1 We assume that all varieties are projective, normal, and defined over $\mathbb{C}$.

2 The number $\text{lct}(X)$ is an algebraic counterpart of the $\alpha$-invariant introduced in [13].
where \(\mathbb{Z}_2 \ast \mathbb{Z}_2\) is the infinite dihedral group.

The assertion of Theorem 1.3 may fail without the generality assumption.

**Example 1.7.** Let \(X\) be a hypersurface in \(\mathbb{P}(1, 1, 2, 6, 9)\) of degree 18 given by the equation
\[
w^2 = t^3 + z^9 + y^{18} + x^{18} \subset \mathbb{P}(1, 1, 2, 6, 9) \cong \text{Proj} \left( \mathbb{C}[x, y, z, t, w] \right),
\]
where \(\text{wt}(x) = \text{wt}(y) = 1, \text{wt}(z) = 2, \text{wt}(t) = 6, \text{wt}(w) = 9\). The hypersurface \(X\) has terminal quotient singularities, and \(-K_X^3 = 1/6\). Arguing as in the proof of Theorem 1.3 we see that
\[
\text{lc}(X) = \sup \left\{ \lambda \in \mathbb{Q} \mid \text{the log pair } (X, \lambda D) \text{ is log canonical for every Weil divisor } D \in | -K_X | \right\},
\]
which easily implies that \(\text{lc}(X) = 17/18\) by Lemma 8.12 and Proposition 8.14 in [9].

Nevertheless, the proof of Theorem 1.3 in [5] and the proof of Theorem 1.3 can also be used to construct explicit examples of Fano threefolds to which Corollaries 1.4 and 1.5 can be applied.

**Example 1.8.** Let \(X\) be a hypersurface in \(\mathbb{P}(1, 2, 2, 3, 7)\) of degree 14 given by the equation
\[
w^2 = t^4 z + y^7 - z^7 + x^{14} \subset \mathbb{P}(1, 2, 2, 3, 7) \cong \text{Proj} \left( \mathbb{C}[x, y, z, t, w] \right),
\]
where \(\text{wt}(x) = 1, \text{wt}(y) = \text{wt}(z) = 2, \text{wt}(t) = 3, \text{wt}(w) = 7\). The hypersurface \(X\) has terminal quotient singularities, and \(-K_X^3 = 1/6\). Arguing as in the proof of Theorem 1.3 we see that
\[
\text{lc}(X) = \sup \left\{ \lambda \in \mathbb{Q} \mid \text{the log pair } (X, \lambda D) \text{ is log canonical} \right\},
\]
where \(D\) is the unique Weil divisor in \(| -K_X |\). Then \(\text{lc}(X) = 1\) by Lemma 8.12 and Proposition 8.14 in [9]. The threefold \(X\) has a Kähler–Einstein metric, and the group Bir(\(X \times X\)) is finite.

The proof of Theorem 1.3 is based on the results obtained in [5], [3], [2], [4], but it is lengthy, because the hypotheses of Theorem 1.3 are satisfied for general members of 90 out of 95 families of quasismooth terminal anticanonically embedded weighted Fano threefolds hypersurfaces (see [7]).

For the convenience of the reader, we organize this paper in the following way:
- we prove Theorem 1.3 in Section 2 omitting the proofs of Lemmas 2.3, 2.10, 2.11;
- we prove auxiliary technical Lemmas 2.3, 2.10, 2.11 in Sections 3, 4, 5, respectively;
- we consider one important generalization of Corollary 1.5 in Section 6.

The author would like to thank J. Howie, J. Kollár, L. O’Carroll, J. Park, A. Pukhlikov, V. Shokurov and the referees for useful comments. The author is grateful to the IHES for hospitality.

2. The proof of main result.

Let \(X\) be a general quasismooth hypersurface in \(\mathbb{P}(1, a_1, a_2, a_3, a_4)\) of degree \(d = \sum_{i=1}^{4} a_i\) with terminal singularities, and let \(\mathfrak{j} \in \{1, \ldots, 95\}\) be the ordinal number of \((a_1, a_2, a_3, a_4)\) in the notation of Table 5 in [7], where \(a_1 \leq a_2 \leq a_3 \leq a_4\). Then \(-K_X^3 \leq 1 \iff \mathfrak{j} \geq 6\).

We suppose that \(\mathfrak{j} \geq 6\), but there is \(D \in | -nK_X |\) such that \((X, \frac{1}{n}D)\) is not log canonical, where \(n\) is a natural number. Then to prove Theorem 1.3 it is enough to derive a contradiction, because the class group of the hypersurface \(X\) is generated by the divisor \(-K_X\).

**Remark 2.1.** Let \(V\) be a variety, let \(B\) and \(B'\) be effective \(\mathbb{Q}\)-Cartier \(\mathbb{Q}\)-divisors on \(V\) such that the singularities of the log pairs \((V, B)\) and \((V, B')\) are log canonical, and let \(\alpha\) be a rational number such that \(0 \leq \alpha \leq 1\). Then the log pair \((V, \alpha B + (1 - \alpha)B')\) is log canonical.

Thus, we may assume that \(D\) is an irreducible surface due to Remark 2.1.

**Lemma 2.2.** The inequality \(n \neq 1\) holds.

**Proof.** Suppose that \(n = 1\). Then the log pair \((X, D)\) is log canonical at every singular point of the threefold \(X\) by Lemma 8.12 and Proposition 8.14 in [9]. Thus, the equality \(a_1 = 1\) holds, because the linear system \(| -K_X |\) consists of a single surface in the case when \(a_1 \neq 1\).

The equality \(a_1 = 1\) holds for 36 values of \(\mathfrak{j} \in \{6, 7, \ldots, 95\}\), but all possible cases are very similar. So for the sake of simplicity, we assume that \(\mathfrak{j} = 14\). Then there is a natural double cover \(\pi: X \to \mathbb{P}(1, 1, 1, 4)\) branched over a general hypersurface \(F \subset \mathbb{P}(1, 1, 1, 4)\) of degree 12.

Suppose that the singularities of the log pair \((X, D)\) are not log canonical at some smooth point \(P\) of the threefold \(X\). Let us show that this assumption leads to a contradiction.
Put $\tilde{D} = \pi(D)$ and $\tilde{P} = \pi(P)$. Counting parameters, we see that $\text{mult}_{\tilde{P}}(F|_{\tilde{D}}) \leq 2$, which is a contradiction, because $(\tilde{D}, \frac{1}{n}F|_{\tilde{D}})$ is not log canonical at $\tilde{P}$ by Lemma 8.12 in [8]. □

**Lemma 2.3.** The log pair $(X, \frac{1}{n}D)$ is log canonical at smooth points of the threefold $X$.

**Proof.** See Section 3. □

Therefore, there is a singular point $O$ of the threefold $X$ such that $(X, \frac{1}{n}D)$ is not canonical at the point $O$. It follows from [7] that $O$ is a singular point of type $\frac{1}{r}(1, a, r-a)$, where $a$ and $r$ are coprime natural numbers such that $r > 2a$ (see Table 5 in [7] for the values of $a$ and $r$).

Let $\alpha: U \to X$ be a blow up of $O$ with weights $(1, a, r-a)$. Then

$$-K_U^3 = -K_X^3 - \frac{1}{r^3}E^3 = -K_X^3 - \frac{1}{ra(r-a)} = \frac{1}{a_1a_2a_3a_4} - \frac{1}{ra(r-a)},$$

where $E$ is the exceptional divisor of $\alpha$. There is a rational number $\mu$ such that

$$\tilde{D} \equiv \alpha^*(D) - \mu E \equiv -nK_U + (n/r - \mu)E,$$

where $\tilde{D}$ is the proper transform of $D$ on $U$. Then it follows from [8] that $\mu > n/r$.

**Lemma 2.5.** The inequality $-K_U^3 \geq 0$ holds.

**Proof.** Suppose that $-K_U^3 < 0$. Let $C$ be a curve in $E$. Then the curve $C$ generates an extremal ray of the cone $\text{NE}(U)$. Moreover, it follows from Corollary 5.4.6 in [5] that there is an irreducible curve $\Gamma \subset U$ such that $\Gamma$ generates the extremal ray of $\text{NE}(U)$ that is different from $\mathbb{R}_{\geq 0}C$, and

$$\Gamma \equiv -K_U \cdot \left( -bK_U + cE \right),$$

where $b > 0$ and $c \geq 0$ are integers (see Remark 5.4.7 in [5]).

Let $T$ be a divisor in $|-K_U|$. Then $\tilde{D} \cdot T$ is effective, because $\tilde{D} \not\equiv T$. However we have

$$\tilde{D} \cdot T \equiv -K_U \cdot \left( -nK_U + (n/r - \mu)E \right) \notin \text{NE}(U),$$

because $\mu > n/r$, $b > 0$, and $c \geq 0$. So we have a contradiction. □

Taking into account the possible values of $(a_1, a_2, a_3, a_4)$, we see that $\mathfrak{J} \notin \{75, 84, 87, 93\}$.

**Lemma 2.6.** The inequality $-K_U^3 \neq 0$ holds.

**Proof.** Firstly, suppose that $-K_U^3 = 0$ and $\mathfrak{J} \neq 82$. Then the linear system $|-rK_U|$ does not have base points for $r \gg 0$ and induces a morphism $\eta: U \to \mathbb{P}(1, a_1, a_2)$ such that the diagram

$$\begin{array}{ccc}
U & \xrightarrow{\eta} & \mathbb{P}(1, a_1, a_2) \\
\alpha \downarrow & & \downarrow \psi \\
X & \xrightarrow{\psi} & \mathbb{P}(1, a_1, a_2)
\end{array}$$

is commutative, where $\psi$ is a natural projection. The morphism $\eta$ is an elliptic fibration. Thus

$$\tilde{D} \cdot C = -nK_U \cdot C + (n/r - \mu)E \cdot C = (n/r - \mu)E \cdot C < 0,$$

where $C$ is a general fiber of $\eta$, which is a contradiction.

Suppose that $-K_U^3 = 0$ and $\mathfrak{J} = 82$. Then $X$ is a hypersurface in $\mathbb{P}(1, 1, 5, 12, 18)$ of degree 36, whose singularities consist of two points $P$ and $Q$ of types $\frac{1}{3}(1, 2, 3)$ and $\frac{1}{2}(1, 1, 5)$, respectively.

We see that either $P = O$, or $Q = O$. The hypersurface $\tilde{X}$ can be given by the equation

$$z^7y + \sum_{i=0}^{6} z^i f_{36-5i}(x, y, z, t) = 0 \subset \mathbb{P}(1, 1, 5, 12, 18) \cong \text{Proj} \left( \mathbb{C}[x, y, z, t, w] \right),$$

where $\text{wt}(x) = 1$, $\text{wt}(y) = 1$, $\text{wt}(z) = 5$, $\text{wt}(t) = 12$, $\text{wt}(w) = 18$, and $f_i$ is a quasihomogeneous polynomial of degree $i$. Then $P$ is is given by the equations $x = z = t = w = 0$.

Suppose that $Q = O$. Then the linear system $|-rK_U|$ has no base points for $r \gg 0$, which leads to a contradiction as in the case when $\mathfrak{J} \neq 82$. So we see that $P = O$.

Let $\tilde{S}$ be the proper transform on $U$ of the surface that is cut out on $X$ by $y = 0$. Then

$$\tilde{S} \equiv \alpha^*(-K_X) - \frac{6}{5}E,$$
and the base locus of the pencil $|−K_U|$ consists of two irreducible curves $L$ and $C$ such that the curve $L$ is contained in the $α$-exceptional surface $E$, and the curve $π(C)$ is the unique base curve of the pencil $|−K_X|$. Then $−K_U ⋅ C = −1/6$ and $−K_U ⋅ L > 0$. We have $μ ≤ n/5$ due to

$$n/5 − μ = \left(−K_U + α^⋆(−5K_X)\right) \cdot S ⋅ D ≥ 0,$$

because it follows from Lemma 8.12 and Proposition 8.14 in [9] that $D ≠ S$. However we know that the inequality $μ > n/5$ holds by [8]. So again we have a contradiction.

Thus, taking into account the equality [24] and possible values of $(a_1, a_2, a_3, a_4)$, we see that $J ⊄ \{11, 14, 19, 22, 28, 34, 37, 39, 49, 52, 53, 57, 59, 64, 66, 70, 72, 73, 78, 80, 81, 86, 88, 89, 90, 92, 94, 95\}$ by Lemma 2.6. So the assertion of Theorem 1.3 is proved for 32 values of $(a_1, a_2, a_3, a_4)$.

Lemma 2.7. The groups Bir$(X)$ and Aut$(X)$ do not coincide.

Proof. Suppose that Bir$(X) = \text{Aut}(X)$. Let $S$ be a general surface in $|−K_U|$. Then it follows from Lemma 5.4.5 in [5] that there is an irreducible surface $T ⊂ U$ such that

- the equivalence $T ∼ cS − bE$ holds, where $c > 1$ and $b ≥ 1$ are natural numbers,
- the scheme-theoretic intersection $T ⋅ S$ is an irreducible and reduced curve $Γ$,
- the curve $Γ$ generates an extremal ray of the cone $\mathbb{NE}(U)$.

The surface $T$ is easy to construct explicitly (see [5]), and the possible values for the natural numbers $c$ and $b$ can be found in [5]. The surface $T$ is determined uniquely by the point $O$.

Put $T = α(T)$. Then it follows from Lemma 8.12 and Proposition 8.14 in [9] that the singularities of the log pair $(X, 1/3T)$ are log canonical. Therefore, we have $D ≠ T$.

Let $P$ be the pencil generated by the effective divisors $nT$ and $cD$. Then the singularities of the log pair $(X, 1/ctP)$ are not canonical, which is impossible due to [5].

It follows from [5] and Lemma 2.7 that $J ⊄ \{11, 21, 29, 35, 50, 51, 55, 62, 63, 67, 71, 77, 82, 83, 85, 91\}$.

Lemma 2.8. The divisor $−K_U$ is nef.

Proof. Suppose that $−K_U$ is not nef. Then it follows from [5] that $J = 47$ and $O$ is a singular point of type $1/5(1, 2, 3)$. The hypersurface $X$ can be given by the equation

$$z^3y + \sum_{i=0}^{3} z^i f_{21−5i}(x, y, z, t) = 0 \subset \mathbb{P}(1, 1, 5, 7, 8) ∼ \text{Proj}\left(\mathbb{C}[x, y, z, t, w]\right),$$

where $\text{wt}(x) = \text{wt}(y) = 1$, $\text{wt}(z) = 5$, $\text{wt}(t) = 7$, $\text{wt}(w) = 8$, and $f_i$ is a general quasihomogeneous polynomial of degree $i$. Let $S$ be the surface on $X$ that is cut out by the equation $y = 0$, and $\bar{S}$ be the proper transform of the surface $S$ on the threefold $U$. Then

$$\bar{S} ≃ α^⋆(−K_X) − \frac{6}{5}E,$$

but the divisor $−3K_U + α^⋆(−5K_X)$ is nef (see [2]). Thus, the inequality $μ ≤ n/5$ holds due to

$$n/5 − μ = \frac{1}{3}\left(−3K_U + α^⋆(−5K_X)\right) \cdot \bar{S} ⋅ \bar{D} ≥ 0,$$

because $D ≠ S$. However we know that $μ > n/5$. So we have a contradiction.

Thus, the divisor $−K_U$ is nef and big, because $−K_U^3 > 0$ by Lemmas 2.5 and 2.6.

Lemma 2.9. The inequality $μ/n − 1/r < 1$ holds.

Proof. We only consider the case when $J = 58$ and $O$ is a singular point of type $1/10(1, 3, 7)$, because the proof is similar in all other cases (cf. Lemma 5.1). Then $X$ can be given by

$$w^2z + wf_{14}(x, y, z, t) + f_{24}(x, y, z, t) = 0 \subset \mathbb{P}(1, 3, 4, 7, 10) ∼ \text{Proj}\left(\mathbb{C}[x, y, z, t, w]\right),$$

where $\text{wt}(x) = 1$, $\text{wt}(y) = 3$, $\text{wt}(z) = 4$, $\text{wt}(t) = 7$, $\text{wt}(w) = 10$, and $f_i$ is a quasihomogeneous polynomial of degree $i$. Let $R$ be the surface on $X$ that is cut out by $t = 0$, and $\bar{R}$ be the proper transform of the surface $R$ on the threefold $U$. Then

$$\bar{R} ≃ α^⋆(−4K_X) − \frac{7}{5}E,$$
and \((X, \frac{1}{n}R)\) is log canonical at \(O\) by Lemma 8.12 and Proposition 8.14 in [9]. Then \(R \neq D\) and \(0 \leq -K_U \cdot R \cdot D = 4n/35 - 2\mu/3,\) because \(-K_U\) is nef. Thus, we have \(\mu \leq 6n/35,\) which implies that \(\mu/n - 1/10 < 1.\) \(\square\)

So the log pair \((U, \frac{1}{n}D + (\mu/n - 1/r)E)\) is not log canonical at some point \(P \in E,\) because

\[
K_U + \frac{1}{n}D \equiv \alpha^*\left(K_X + \frac{1}{n}D\right) + (1/r - \mu/n)E.
\]

**Lemma 2.10.** The threefold \(U\) is smooth at the point \(P.\)

*Proof.* See Section [6]. \(\square\)

Thus, the inequality \(\text{mult}_P(\bar{D}) > n + n/r - \mu\) holds. But it follows from [5] that

- either \(d = 2r + a_j\) for some \(j,\) and there is a quadratic involution \(\tau \in \text{Bir}(X)\) induced by \(O,\)
- or \(d = 3r + a_j\) for some \(j,\) and there is an elliptic involution \(\tau \in \text{Bir}(X)\) induced by \(O,\)

where \(d = \sum_{i=1}^4 a_i.\)

**Lemma 2.11.** The inequality \(d \neq 2r + a_j\) holds for every \(j \in \{1, 2, 3, 4\}.\)

*Proof.* See Section [5]. \(\square\)

Thus, it follows from [5] that there is \(j \in \{1, 2, 3, 4\}\) such that \(d = 3r + a_j.\)

**Remark 2.12.** Let \(V\) be a threefold with isolated singularities, let \(B \neq T\) be effective irreducible divisors on the threefold \(V,\) and let \(H\) be a nef divisor on the threefold \(V.\) Put

\[
B : T = \sum_{i=1}^r \epsilon_i L_i + \Delta,
\]

where \(L_i\) is an irreducible curve, \(\epsilon_i\) is a non-negative integer, and \(\Delta\) is an effective one-cycle whose support does not contain the curves \(L_1, \ldots, L_r.\) Then \(\sum_{i=1}^r \epsilon_i H \cdot L_i \leq B \cdot T \cdot H.\)

It follows from Lemma [2.11] that \(J \in \{7, 20, 23, 36, 40, 44, 61, 76\}\) (see [5]).

**Lemma 2.13.** The case \(J \in \{7, 20, 36\}\) is impossible.

*Proof.* Suppose that \(J \in \{7, 20, 36\}.\) Then \(a_1 = 1,\) and it follows from Lemma [2.11] that \(O\) is a singular point of type \(\frac{1}{a_2}(1, 1, a_2 - 1).\) Then \(-rK_U\) induces a birational morphism \(\sigma : U \rightarrow V\) such that \(\sigma\) contracts smooth rational curves \(C_1, \ldots, C_l,\) and \(V\) is a hypersurface in \(\mathbb{P}(1, 1, a_3, 2a_4, 3a_4)\) of degree \(6a_4,\) where \(l = d(d - a_4)/a_3.\) Let \(T\) be the surface in \(|-K_U|\) that contains \(P.\)

Suppose that \(P \notin U \cup_{i=1}^l C_i.\) Then it follows from the proof of Theorem 5.6.2 in [4] that there are natural number \(s > 0\) and a surface \(H \in \{|-s2a_4K_U|\}\) such that

\[
s2a_4(-nK_X^3 - \mu/(a_2 - 1)) = \bar{D} \cdot T \cdot H \geq \text{mult}_P(\bar{D})s > s(n + n/a_2 - \mu)s,
\]

which is impossible, because \(\mu > n/a_2.\) So we may assume that \(P \in C_1.\)

Put \(\bar{D} \cdot T = mc + \Delta,\) where \(m\) is a non-negative integer, and \(\Delta\) is an effective cycle such that the support of \(\Delta\) does not contain the curve \(C_1\). The curve \(C_1\) is a smooth rational curve such that \(\alpha^*(-K_X) \cdot C_1 = 2/a_2\) and \(E \cdot C_1 = 2.\)

It follows from [5] that there is a surface \(R \in |-a_3K_U|\) such that \(R\) contains \(C_1,\) but \(R\) does not contain components of the cycle \(\Delta\) passing through the point \(P.\) Then

\[
a_3(-nK_X^3 - \mu/(a_2 - 1)) = R \cdot \Delta \geq \text{mult}_P(\Delta) > n + n/a_2 - \mu - m,
\]

which implies that \(m > a_3n/a_4,\) because \(\mu > n/a_2.\) Therefore, we have

\[
a_3n/a_4 < m \leq \frac{-dnK_X \cdot \alpha(C_1)}{a_1a_2a_3a_4} = \frac{dn}{2a_1a_3a_4}
\]

by Remark [2.12] because \(-K_X \cdot \alpha(C_1) = 2/a_2.\) The inequalities just obtained imply that \(J = 7.\)

Let \(\psi : X \dashrightarrow \mathbb{P}(1, a_1, a_2)\) be a natural projection. The fiber of \(\psi\) over \(\psi(P)\) consists of two irreducible components, and one of them is \(C_1.\) Let \(Z\) be the other component of this fiber. Then

\[
C_1^2 = -2, \quad C_1 \cdot Z = 2, \quad Z^2 = -4/3
\]

on the surface \(T.\) Put \(\Delta = \bar{m}Z + \Omega,\) where \(\bar{m}\) is a non-negative integer and \(\Omega\) is an effective one-cycle whose support does not contain the curve \(Z.\) Then

\[
4n/3 - 2\mu - 5\bar{m}/3 = (Z + C_1) \cdot \Omega > 3n/2 - \mu - m,
\]
and \(4\bar{m}/3 \geq 2m - 5n/6\), because \(\Omega \cdot Z \geq 0\). The inequalities just obtained immediately imply that the inequality \(\mu \leq n/2\) holds. So we have a contradiction, because \(\mu > n/2\). \(\square\)

Hence, it follows from Lemmas 2.11 and 2.13 that \(\mathcal{J} \in \{23, 40, 44, 61, 76\}\) and \(d = 3r + a_j\), where \(r = a_3 > 2a\) and \(1 \leq j \leq 2\). Then \(X\) has a singular point \(Q\) of type \(\frac{1}{3}(1, \bar{a}, \bar{r} - \bar{a})\) such that \(\delta \geq \delta\).

\(-K^3_X = \frac{1}{ra(r - a)} + \frac{1}{\bar{r}\bar{a}(\bar{r} - \bar{a})}\),

where \(\bar{r} = a_4 > 2\bar{a}\) and \(\bar{a} \in \mathbb{N}\). It follows from [5] that there is a commutative diagram

\[
\begin{array}{cccc}
V & U & \gamma & W \\
\downarrow & \alpha & \downarrow & \downarrow \\
\mathbb{P}(1, a_1, a_2, 2a_4, 3a_4) & X & \mathbb{P}(1, a_1, a_2, 2a_4) & \mathbb{P}(1, a_1, a_2), \\
\downarrow & \chi & \downarrow & \xi \\
\end{array}
\]

where \(\xi, \chi, \psi, \eta\) are projections, \(\eta\) is an elliptic fibration, \(\gamma\) is a weighted blow up of a point that dominates the point \(Q\) with weights \((1, \bar{a}, \bar{r} - \bar{a})\), and \(\sigma\) is a birational morphism that contracts smooth curves \(C_1, \ldots, C_l\) such that \(V\) is a hypersurface in \(\mathbb{P}(1, a_1, a_2, 2a_4, 3a_4)\) of degree \(6a_4\), where \(l = d(d - a_4)/(a_1a_2)\). Let \(L\) be a curve in \(|\mathcal{O}_{\mathbb{P}(1,a_1-a_3)}(1)|\), where \(E \cong \mathbb{P}(1,a_1-a_3)\).

**Lemma 2.14.** Suppose that \(P \notin L\). Then \(\mu > na(r + 1)/(r^2 + ar)\).

**Proof.** There is a unique curve \(C \in |\mathcal{O}_{\mathbb{P}(1,a_1-a_3)}(a)|\) such that \(P \in C\). Put \(\bar{D}|_E = \delta C + \Upsilon \equiv r\mu L\), where \(\delta\) is a non-negative integer and \(\Upsilon\) is an effective cycle such that \(C \notin \operatorname{Supp}(\Upsilon)\). Then \((= \mu - a\delta)L \cdot C = C \cdot \Upsilon \geq \operatorname{mult}_p(\Upsilon) > n + n/r - \mu - \delta\), which implies that \(\mu > na(r + 1)/(r^2 + ar)\), because \(\delta \leq \mu/a\). \(\square\)

Let \(T\) be a surface in \(|-K_U|\). Then \(-K_U \cdot T \cdot \bar{D} > 0\), which implies that \(\mu \leq -na(r-a)K^3_X\).

**Lemma 2.15.** The point \(P\) is not contained in the surface \(T\).

**Proof.** Suppose that \(P\) is contained in the surface \(T\). Then \(P\) is not contained in the base locus of the pencil \(|-a_1K_U|\), because the base locus of the pencil \(|-a_1K_U|\) does not contain smooth points of the surface \(E\). The point \(P\) is not contained in the union \(\bigcup_{i=1}^l C_i\), because \(P \notin T\).

The proof of Theorem 5.6.2 in [3] implies the existence of a surface \(H \in |-s_2a_1a_4K_U|\) such that \(s_2a_1a_4(-nK^3_X - \mu/a_2) = \bar{D} \cdot H \cdot T > \operatorname{mult}_p(\bar{D}) s > s(n + n/r - \mu) s\), where \(s\) is a natural number, which is impossible, because \(\mu > n/r\). \(\square\)

We have \(T|_E \sim \mathcal{O}_{\mathbb{P}(1,a_1-a_3)}(1)\). Thus, taking into account that \(\mathcal{J} \in \{7, 20, 23, 36, 40, 44, 61, 76\}\), we see that \(\mathcal{J} \in \{23, 44\}\) by Lemmas 2.14 and 2.13, because \(\mu \leq -na(r-a)K^3_X\).

Let \(S\) be a surface in \(|-a_1K_U|\) that contains \(P\). Then \(\bar{D} \neq S\), because \(\mu > n/r\).

**Lemma 2.16.** The point \(P\) is contained in \(\bigcup_{i=1}^l C_i\).

**Proof.** Suppose that \(P \notin \bigcup_{i=1}^l C_i\). Then the proof of Theorem 5.6.2 in [3] implies that \(s_2a_1a_4(-nK^3_X - \mu/a_2) = \bar{D} \cdot H \cdot S > \operatorname{mult}_p(\bar{D}) s > s(n + n/r - \mu) s\) for some \(s \in \mathbb{N}\) and a surface \(H \in |-s_2a_4K_U|\), which is impossible, because \(\mu > n/r\). \(\square\)

We may assume that \(P \in C_1\). Put \(\bar{D} \cdot S = mC_1 + \Delta\), where \(m\) is a non-negative integer, and \(\Delta\) is an effective cycle whose support does not contain \(C_1\). Then it follows from Remark 2.12 that the inequality \(m \leq nd/(a_2d - a_2a_3)\) holds, because \(-K_X \cdot a(C_1) = (d - a_3)/(a_3a_4)\).

It follows from the proof of Theorem 5.6.2 in [3] that there is \(R \in |-s_2a_4K_U|\) such that \(s_2a_1a_4(-nK^3_X - \mu/a_2) = R \cdot \Delta \geq \operatorname{mult}_p(\Delta) s > s(n + n/r - \mu - m)\), where \(s \in \mathbb{N}\). However we have \(m \leq nd/(a_2d - a_2a_3)\), which implies that \(\mathcal{J} = 23\).
Therefore, we proved that $X$ is a hypersurface $\mathbb{P}(1,2,3,4,5)$ of degree 14 and $O$ is a singular point of type $\frac{1}{3}(1,1,3)$. Let $M$ be a general surface in the linear system $|−3K_X|$ that passes through the point $P$. Then $S \cdot M = C_1 + Z_1$, where $Z_1$ is a curve such that $−K_U \cdot Z_1 = 1/5$. Put $\bar{D} \cdot S = mC_1 + \bar{m}Z_1 + \gamma$,

where $\bar{m}$ is a non-negative integer, and $\gamma$ is an effective cycle, whose support does not contain the curves $C_1$ and $Z_1$. Then $m < 7n/15$ by Remark 2.12. But $\mu > n/4$ and $7n/10 - 6\mu/3 - 3\bar{m}/5 = M \cdot \gamma \geq \text{mult}_P(\gamma) > 5n/4 - \mu - m$,

because $P \not\in Z_1$. The inequality obtained implies a contradiction.

Therefore, the assertion of Theorem 1.3 is completely proved.

3. Non-singular points.

In this section we prove the assertion of Lemma 2.3. Let us use the assumptions and notation of Lemma 2.3. Take an arbitrary smooth point $P$ of the threefold $X$.

**Lemma 3.1.** Suppose that $a_4$ divides $d$, $a_1 \neq a_2$, and $−a_2a_3K_X^3 \leq 1$. Then $\text{mult}_P(D) \leq n$.

**Proof.** Suppose that $\text{mult}_P(D) > n$. Let $L$ be the base curve of $|−a_1K_X|$, and $T$ be a surface in the linear system $|−K_X|$. Then $D \cdot T$ is an effective one-cycle, and $\text{mult}_P(L) = 1$.

Suppose that $P \in L$. Let $R$ be a general surface in $|−a_1K_X|$. Put $D \cdot T = mL + \Delta$, where $m$ is non-negative integer, and $\Delta$ is an effective cycle whose support does not contain $L$. Then $−a_1(n − a_1m)K_X^3 = D \cdot T \cdot R − mR \cdot L = R \cdot \Delta \geq \text{mult}_P(\Delta) > n − m$,

which is impossible, because $−a_1K_X^3 \leq 1$. Thus, we see that $P \not\in L$.

Suppose that $P \in T$. It follows from Theorem 5.6.2 in [5] that $ns > −sa_2a_3nK_X^3 = D \cdot S \cdot T \geq \text{mult}_P(D)s > ns$

for some $s \in \mathbb{N}$ and some surface $S \in |−sa_2a_3K_X|$. Hence, we see that $P \not\in T$.

Let $G$ be a general surface in $|−a_2K_X|$ that contains $P$. Then $G \cdot D$ is an effective cycle, but it follows from Theorem 5.6.2 in [5] that there are $s \in \mathbb{N}$ and $H \in |−sa_3K_X|$ such that $ns > −sa_2a_3nK_X^3 = D \cdot H \cdot G \geq \text{mult}_P(D)s > ns$,

because $−a_2a_3K_X^3 \leq 1$. So we have a contradiction. \hfill \Box

**Lemma 3.2.** Suppose that $a_4$ divides $d$, $1 = a_1 \neq a_2$, and $−a_3K_X^3 \leq 1$. Then $\text{mult}_P(D) \leq n$.

**Proof.** Suppose that $\text{mult}_P(D) > n$. Then arguing as in the proof of Lemma 3.1 we see that the point $P$ is not contained in the base curve of the pencil $|−K_X|$.

Let $T$ be a general surface in $|−K_X|$ that contains $P$. Then Theorem 5.6.2 in [5] implies that there are $s \in \mathbb{N}$ and $S \in |−sa_3K_X|$ such that $ns > −sa_3nK_X^3 = D \cdot S \cdot T \geq \text{mult}_P(D)s > ns$. \hfill \Box

**Lemma 3.3.** Suppose that $a_1 \neq a_2$ and $−a_3a_4K_X^3 \leq 1$. Then $\text{mult}_P(D) \leq n$.

**Proof.** Suppose that $\text{mult}_P(D) > n$. The proof of Lemma 3.2 implies that $a_1 \neq 1$. Arguing as in the proof of Lemma 3.1 we see that $P$ is not contained in the unique surface of $|−K_X|$.

Let $S$ be a surface in $|−a_1K_X|$ that contains $P$. Then we may assume that $\text{mult}_P(S) \leq a_1$, because $P \not\in T$ and $X$ is sufficiently general. Thus, we have $S \not\in D$.

It follows from Theorem 5.6.2 in [5] that there are $s \in \mathbb{N}$ and $H \in |−sa_4K_X|$ such that $H$ has multiplicity at least $s > 0$ at $P$ and contains no components of $D \cdot S \cdot H$ passing through $P$. Then $ns > −sa_1a_4nK_X^3 = D \cdot S \cdot H \geq \text{mult}_P(D)s > ns$,

because $−a_1a_4K_X^3 \leq 1$. So we have a contradiction. \hfill \Box

Taking into account the possible values of $(a_1,a_2,a_3,a_4)$, we see that $\text{mult}_P(D) \leq n$ whenever

$\mathcal{J} \notin \{6,7,8,9,10,12,13,14,16,18,19,21,22,23,24,25,32,33,38\}$

by Lemmas 3.1 3.2 3.3. The log pair $(X, \frac{1}{n}D)$ is log canonical at $P$ if $\text{mult}_P(D) \leq n$ (see [9]).

**Lemma 3.4.** Suppose that $\mathcal{J} = 18$. Then $(X, \frac{1}{n}D)$ is log canonical at $P$.
Proof. Suppose that the log pair \((X, \frac{1}{2}D)\) is log canonical at the point \(P\). Let us show that this assumption leads to a contradiction. Note that the inequality \(\text{mult}_P(D) > n\) holds.

The threefold \(X\) is a hypersurface in \(\mathbb{P}(1, 2, 2, 3, 5)\) of degree 12, whose singularities consist of six points of type \(\frac{1}{2}(1, 1, 1)\), and a point \(O\) of type \(\frac{1}{5}(1, 2, 3)\). It follows from [2] that the diagram

\[
\begin{array}{c}
\alpha \downarrow \\
X \rightarrow \mathbb{P}(1, 2, 2) \\
\beta \downarrow \\
U \leftarrow W
\end{array}
\]

commutes, where \(\alpha\) is a weighted blow up of the point \(O\) with weights \((1, 2, 3)\), \(\beta\) is a weighted blow up with weights \((1, 1, 3)\) of a singular point of type \(\frac{1}{2}(1, 1, 2)\), and \(\eta\) is an elliptic fibration.

Let \(C\) be a fiber of the projection \(\psi\) that passes through the point \(P\), and \(L\) be its irreducible reduced component. We have \(-K_X \cdot C = 4/5\). But the number \(-5K_X \cdot L\) is natural if \(L\) contains no points of type \(\frac{1}{2}(1, 1, 1)\). Then \(C = 2L\) whenever \(C\) contains a point of type \(\frac{1}{2}(1, 1, 1)\).

Let \(T\) be the surface in \([\sim K_X]\), and let \(S\) and \(\hat{S}\) be general surfaces in \([\sim 2K_X]\) that passes through the point \(P\). Then \(S\) and \(\hat{S}\) are irreducible and \(S \supset L \subset \hat{S}\), but \(S \neq D \neq \hat{S}\). Suppose now that \(L\) is contained in \(T\). Then \(C = 2L\) and \(-K_X \cdot L = 2/5\), but the singularities of the curve \(L\) consists of at most double points. Put \(D|_T = mL + \hat{Y}\), where \(m\) is a non-negative integer, and \(\hat{Y}\) is an effective cycle whose support does not contain \(L\). Then

\[
2n/5 - 4m/5 = S \cdot \hat{Y} \geq \text{mult}_P(\hat{Y}) \geq \text{mult}_P(D) - \text{mult}_P(L) > n - 2m,
\]

which implies that \(m > n/2\). But \(m \leq n/2\) by Remark 2.12, which implies that \(L \not\subset T\).

Suppose that \(C = L\). Then \(\text{mult}_P(L) \leq 2\). Put \(D \cdot \hat{S} = mC + \hat{Y}\), where \(m\) is a non-negative integer and \(\hat{Y}\) is an effective cycle whose support does not contain \(C\). Then

\[
4n/5 - 8m/5 = S \cdot \hat{Y} \geq \text{mult}_P(\hat{Y}) > n - 2m,
\]

which implies that \(m > n/2\). But \(m \leq n/2\) by Remark 2.12, which implies that \(C \neq L\).

The curve \(L\) does not pass through a point of type \(\frac{1}{2}(1, 1, 1)\), and it follows from the generality of the threefold \(X\) that \(C = L + Z\), where \(Z\) is an irreducible curve such that \(Z \neq L\).

Put \(D|_S = mL + mZ + \Omega\), where \(mL\) and \(mZ\) are non-negative integers and \(\Omega\) is an effective cycle whose support does not contain \(L\) and \(Z\). We may assume that \(-K_X \cdot L \leq -K_X \cdot Z\), which implies that either \(-K_X \cdot L = 1/5\) and \(-K_X \cdot Z = 3/5\), or \(-K_X \cdot L = -K_X \cdot Z = 2/5\).

Suppose that \(-K_X \cdot L = 2/5\). Then \(L\) and \(Z\) are smooth outside of \(O\), and

\[
4n/5 - 4mL/5 - 4mZ/5 = \hat{S}|_S \cdot \Omega \geq \text{mult}_P(\hat{Y}) > n - mL - mC,
\]

which implies that \(mL + mC > n\). But \(mL + mC \leq n\) by Remark 2.12.

Thus, we have \(-K_X \cdot L = 1/5\). The hypersurface \(X\) can be given by an equation

\[
w^2z + wg(x, y, z, t) + h(x, y, z, t) = 0 \subset \mathbb{P}(1, 2, 2, 3, 5) \cong \text{Proj}(\mathbb{C}[x, y, z, t, w]),
\]

where \(w(x) = 1\), \(w(y) = w(z) = 2\), \(w(t) = 3\), \(w(w) = 5\), and \(g\) and \(h\) are quasihomogeneous polynomials of degree 7 and 12, respectively.

Let \(R\) be a surface on the threefold \(X\) that is cut out by \(z = 0\), and let \(\bar{R}\) and \(\bar{L}\) be proper transforms of \(R\) and \(L\) on \(U\), respectively. Then \(\bar{R} \cdot \bar{L} < 0\), which implies that \(L \subset R \supset Z\), and the curve \(L\) is contracted by the projection \(X \twoheadrightarrow \mathbb{P}(1, 2, 2, 3)\) to a point.

Let \(\bar{Z}\) be the proper transform of the curve \(Z\) on the threefold \(U\), let \(\pi: \bar{R} \to R\) be a birational morphism induced by \(\alpha\), and let \(\bar{E}\) be the curve on the surface \(\bar{R}\) that is contracted by \(\pi\). Then

\[
L^2 = -1, \quad \bar{L} \cdot \bar{Z} = \bar{L} \cdot \bar{E} = 1, \quad \bar{Z}^2 = -1/3, \quad \bar{E}^2 = -35/6, \quad \bar{Z} \cdot \bar{E} = 4/3
\]
on the surface \(\bar{R}\), which implies that \(L^2 = -29/35, \quad \bar{L} \cdot \bar{Z} = 43/35, \quad \bar{Z}^2 = -1/3\) on the surface \(R\).

Suppose that \(P \in L \cap Z\). Then \(mL + 3mC \leq 5n\) by Remark 2.12, but

\[
n/5 + 29mL/35 - 43mZ/35 = \Omega \cdot L > n - mL - mZ, \quad 2n/5 - 43mL/35 + mZ/35 = \Omega \cdot Z > n - mL - mZ,
\]

which leads to a contradiction. Hence, either \(L \not\supset P \not\in Z\), or \(Z \not\supset P \not\in L\).

Suppose that \(Z \not\supset P \not\in L\). Then \(\Omega \cdot Z > n - mZ\) and \(\Omega \cdot L \geq 0\), which implies a contradiction. Thus, we see that \(L \not\supset P \not\in L\). Then we have

\[
n/5 + 29mL/35 - 43mZ/35 = \Omega \cdot L > n - mL, \quad 2n/5 - 43mL/35 + mZ/35 = \Omega \cdot Z \geq 0,
\]
which implies that $m_L < n$. Now it follows from Theorem 7.5 in [9] that the log pair

$$
\left( R, L + \frac{mC}{n} + \frac{1}{n} \Omega \right)
$$

is not log canonical at the point $P$. Then $\text{mult}_P(\Omega_L) > n$ by Theorem 7.5 in [9], which implies that the inequality $\Omega \cdot L > n$ holds. The inequality $\Omega \cdot L > n$ leads to a contradiction.

**Lemma 3.5.** Suppose that $\mathfrak{I} = 6$. Then $\text{mult}_P(D) \leq n$.

**Proof.** Suppose that $\text{mult}_P(D) > n$. It follows from [2] that the threefold $X$ has two quotient singular points $O_1$ and $O_2$ of type $\frac{1}{2}(1, 1, 1)$ such that there is a commutative diagram

$$
\begin{array}{ccc}
V & \xrightarrow{\sigma} & U \\
| & | & \gamma \\
\xi & \xrightarrow{\psi} & \eta \\
| & | & | \\
\mathbb{P}(1, 1, 1, 4) & \xrightarrow{\chi} & \mathbb{P}(1, 1, 1),
\end{array}
$$

where $\xi, \psi$ and $\chi$ are projections, $\alpha$ is a blow up of $O_1$ with weights $(1, 1, 1)$, $\gamma$ is a blow up with weights $(1, 1, 1)$ of the point that dominates $O_2$, $\eta$ is an elliptic fibration, $\omega$ is a double cover, and $\sigma$ is a birational morphism that contracts 48 irreducible curves $C_1, \ldots, C_{48}$.

The threefold $U$ contains 48 curves $Z_1, \ldots, Z_{48}$ such that $\alpha(Z_i) \cup \alpha(C_i)$ is a fiber of $\psi$ over the point $\psi(C_i)$. Let $L$ be a fiber of the projection $\psi$ that passes through the point $P$, and let $T_1$ and $T_2$ be general surfaces in $| - K_X |$ that contain $P$.

Suppose that $L$ is irreducible. Put $D \cdot T_1 = mL + \Upsilon$, where $m$ is a non-negative integer and $\Upsilon$ is an effective cycle whose support does not contain $\text{mult}_P(D \cdot T_2) > n - m \text{mult}_P(L)$,

which implies that $L$ is singular at the point $P$. Then there is a surface $T \in | - K_X |$ that is singular at the point $P$. Let $S$ be a general surface in $| - 2K_X |$ that contains $P$. Then

$$
2n = D \cdot T \cdot S \geq \text{mult}_P(D \cdot T) > 2n,
$$

which is a contradiction. Hence, the curve $L$ is reducible.

We have $L = C_i \cup \bar{Z}_i$. Put $D \cdot T_1 = m_1C_i + m_2\bar{Z}_i + \Delta$, where $m_1$ and $m_2$ are non-negative integers and $\Delta$ is an effective cycle whose support does not contain $C_i$ and $\bar{Z}_i$.

In the case when $P \in C_i \cap \bar{Z}_i$, there is $T \in | - K_X |$ such that $T$ singular at $P$, and we can obtain a contradiction as above. So we may assume that $P \in C_i$ and $P \notin \bar{Z}_i$. Then

$$
n - m_1/2 - m_2/2 = (\bar{C}_i + \bar{Z}_i) \cdot \Delta \geq \text{mult}_P(\Delta) > n - m_1 \text{mult}_P(C_i) = n - m_1,
$$

because $\bar{C}_i$ is smooth. Hence, we see that $m_1 > m_2$. But we have

$$
n - m_1 \leq \Delta \cdot \bar{Z}_i = n/2 - m_1 \Delta \cdot \bar{Z}_i - m_2\bar{Z}_i^2 = n/2 - 2m_1 + 3m_2/2 < n/2 - m_1/2,
$$

which gives $m_1 > m_2 > n$. But $m_1 + m_2 \leq 2n$ by Remark 2.12. So we have a contradiction. □

Arguing as in the proofs of Lemmas 3.4 and 3.5 we see that $(X, \frac{1}{n}D)$ is log canonical at $P$ for $\mathfrak{I} \in \{7, 8, 9, 10, 12, 13, 14, 16, 19, 20, 22, 23, 24, 25, 32, 33, 38\}$, which completes the proof Lemma 2.3.

4. Singular points.

In this section we prove the assertion of Lemma 2.10. Let us use the assumptions and notation of Lemma 2.10. Suppose that $P$ is a singular point of $U$. Let us derive a contradiction.

The point $P$ is a singular point of type $\frac{1}{n}(1, a, \bar{r} - \bar{a})$, where $\bar{a}$ and $\bar{r}$ are coprime natural numbers such that $\bar{r} > 2\bar{a}$. Let $\beta: W \to U$ be a blow up of $P$ with weights $(1, a, \bar{r} - \bar{a})$. Then

$$
-K^3_W = -K^3_X - \frac{1}{ra(r - a)} - \frac{1}{\bar{r}a(\bar{r} - \bar{a})}.
$$
Let $\tilde{D}$ be the proper transform of $D$ on $W$. There is a rational number $\nu$ such that

$$\tilde{D} \equiv (\alpha \circ \beta)^*(-nK_X) - \mu\beta^*(E) - \nu G,$$

where $G$ is the $\beta$-exceptional divisor. Then

$$K_W + \frac{1}{n}\tilde{D} + (\mu/n - 1/r)\tilde{E} \equiv \beta^*(K_U + \frac{1}{n}\tilde{D} + (\mu/n - 1/r)E) - \epsilon G \equiv -\epsilon G,$$

where $\tilde{E}$ is a proper transform of $E$ on the threefold $W$, and $\epsilon \in \mathbb{Q}$. Then $\epsilon > 0$ due to \[5\].

**Lemma 4.1.** The inequality $-K_W^3 \neq 0$ holds.

**Proof.** Suppose that $-K_W^3 = 0$. Then it follows from \[2\] that the linear system $|-rK_W|$ induces an elliptic fibration $\eta$: $W \to Y$ for $r > 0$. Then $0 \leq \tilde{D} \cdot C = -\epsilon G \cdot C < 0$, where $C$ is a general fiber of the elliptic fibration $\eta$. So we have a contradiction. \[\square\]

Thus, it follows from \[2\] that either $-K_W^3 < 0$, or $-K_W$ is nef and big.

**Lemma 4.2.** Suppose that $-K_W^3 < 0$. Then $-K_W$ is not big.

**Proof.** Suppose that $-K_W$ is big. Then it follows from \[2\] that we have the following possibilities:

- the equality $\mathcal{J} = 25$ holds, and $O$ is a singular point of type $\frac{1}{3}(1, 3, 4)$;
- the equality $\mathcal{J} = 43$ holds, and $O$ is a singular point of type $\frac{1}{3}(1, 4, 5)$;

but both cases are similar. So we assume that $\mathcal{J} = 43$. Then $-K_W - 4\beta^*(K_U)$ is nef (see \[2\]), and there is a surface $H$ in the linear system $|-2K_X|$ such that

$$\tilde{H} \equiv (\alpha \circ \beta)^*(-2K_X) - \frac{11}{9}\beta^*(E) - \frac{3}{2}G,$$

where $\tilde{H}$ is a proper transform of the surface $H$ on the threefold $W$. Thus, we have

$$0 \leq \tilde{H} \cdot \tilde{D} \cdot \left(-K_W - 4\beta^*(K_U)\right) = 5n/9 - 11\mu/4 - \nu,$$

which is impossible, because $\nu - n/3 + 3\mu/4 = n\epsilon > 0$ and $\mu > n/9$. \[\square\]

Let $T$ be a surface in $|-K_X|$, and $\mathcal{P}$ be the pencil generated by the divisors $nT$ and $D$. Then

$$(4.3) \quad \mathcal{B} \equiv -nK_W \equiv (\alpha \circ \beta)^*(-nK_X) - \frac{n}{r}\beta^*(E) - \frac{n}{r}G,$$

where $\mathcal{B}$ is the proper transforms of the pencil $\mathcal{P}$ on the threefold $W$.

**Lemma 4.4.** The divisor $-K_W$ is nef and big.

**Proof.** Suppose that the divisor $-K_W$ is not nef and big. Then $-K_W^3 < 0$, but $-K_W$ is not big by Lemma 4.2. Then the equivalence \[4.3\] almost uniquely determines the pencil $\mathcal{P}$ due to \[4\].

All possible cases are similar. So we assume that $\mathcal{J} \in \{45, 48, 58, 69, 74, 79\}$. Then $O$ is a singular point of type $\frac{1}{a_4}(1, a_1, a_3)$, and $X$ can be given by an equation

$$w^2z + wf(x, y, z, t) + g(x, y, z, t) = 0 \subset \mathbb{P}(1, a_1, a_2, a_3, a_4) \cong \text{Proj}(\mathbb{C}[x, y, z, t, w]),$$

where $\text{wt}(x) = 1$, $\text{wt}(y) = a_1$, $\text{wt}(z) = a_2$, $\text{wt}(t) = a_3$, $\text{wt}(w) = a_4$, and $f$ and $g$ are polynomials.

Let $S$ be a surface that is cut out on the threefold $X$ by $z = 0$, and $\mathcal{M}$ be a pencil generated by the divisors $a_2T$ and $S$. Then it follows from \[4\] that either $\mathcal{P} = \mathcal{M}$, or $\mathcal{P} = |-a_1K_X|$. Suppose that $\mathcal{P} = |-a_1K_X|$. Then $\mu = n/a_1$, which is impossible, because $\mu > n/a_4$.

We see that $\mathcal{P} = \mathcal{M}$. Let $M$ be a divisor in $\mathcal{M}$, and $\tilde{M}$ be its proper transform on $U$. Then

$$\tilde{M} \equiv \alpha^*(M) - \frac{a_3}{a_4}E$$

in the case when $M \neq S$, but $\mu > n/a_4$. Thus, we see that $D = S$, but $(X, \frac{a_2}{a_4}S)$ is log canonical at the point $O$ by Lemma 8.12 and Proposition 8.14 in \[9\], which is a contradiction. \[\square\]

Taking into account the possible values of $(a_1, a_2, a_3, a_4)$, we see that

$$\mathcal{J} \in \{8, 12, 13, 16, 20, 24, 25, 26, 31, 33, 36, 38, 46, 47, 48, 54, 56, 58, 65, 74, 79\}$$

by Lemmas 4.1, 4.2, and 4.4 (see \[2\]).
Lemma 4.5. The case $\mathfrak{I} \not\in \{12, 13, 20, 25, 31, 33, 38, 58\}$ is impossible.

Proof. Suppose that $\mathfrak{I} \not\in \{12, 13, 20, 25, 31, 33, 38, 58\}$. Then $r = a_4, r - a = a_3, \bar{r} = r - a, \bar{a} = a,$ and $ne = \nu - (\bar{r} - \bar{a})(n/r - \mu)/\bar{r} - n/\bar{r}$. We may assume that $\mathfrak{I} \neq 24$, because the case $\mathfrak{I} = 24$ can be considered in a similar way. Then $X$ can be given by the equation

$$w^2z + wf(x, y, z, t) + g(x, y, z, t) = 0 \subset \mathbb{P}(1, a_1, a_2, a_3, a_4) \cong \text{Proj}(\mathbb{C}[x, y, z, t, w]),$$

where $\text{wt}(x) = 1, \text{wt}(y) = a, \text{wt}(z) = d - 2a_4, \text{wt}(t) = a_3, \text{wt}(w) = a_4$, the point $O$ is given by the equations $x = y = z = t = 0$, and $f$ and $g$ are quasihomogeneous polynomials. Then

$$R \equiv (\alpha \beta)^*( - a_2K_X) - \frac{d-r}{r} - \beta^*(E) - \frac{\bar{r} - \bar{a}}{\bar{r} - \bar{a}}G,$$

where $R$ is a proper transform on $W$ of the surface cut out on $X$ by $z = 0$. Then $D \neq R$, and

$$\frac{\sum a_i}{a_1a_2a_3} - \frac{\mu(d-r)}{a(r-a)} = -K_W \cdot D \cdot R \geq 0,$$

which implies that $\mu < n/r$, because $\epsilon > 0$. However we know that $\mu > n/r$. \qed

So, the divisor $-K_W$ is nef and big, and $\mathfrak{I} \in \{12, 13, 20, 25, 31, 33, 38, 58\}$, which implies that $r = a_4, r - a = a_3, \bar{a} = a_1, \bar{r} = \bar{a} = a_2, a_2 \neq a_3, n = \nu + (r - 2a)\mu/(r-a) - 2n/r$ due to \cite{2}. Then $W$ has a singular point $\bar{P} \neq P$ of type $\frac{1}{r}(1, \bar{a}, \bar{r} - \bar{a})$ such that the diagram

$$\begin{array}{ccc}
U & \xrightarrow{\beta} & W \\
\alpha| & & | \gamma \\
X & \xrightarrow{\psi} & \mathbb{P}(1, a_1, a_2)
\end{array}$$

commutes, where $\psi$ is a natural projection, $\gamma$ be a blow up of the point $\bar{P}$ with weights $(1, \bar{a}, \bar{r} - \bar{a})$, and $\eta$ is an elliptic fibration. Let $F$ be the exceptional divisor of $\gamma$, and $\bar{G}$ be the proper transform of the divisor $G$ on the threefold $V$. Then $F$ and $\bar{G}$ are sections of $\eta$, and $G \not\equiv \bar{P} \not\equiv \bar{E}.$

It follows from the inequality $-K_W \cdot D \geq 0$ and the proof of Lemma \cite{2} that $\epsilon < 1$, which implies that the log pair $(W, \frac{1}{n}D + (\mu/n - 1/r)E + \epsilon G)$ is not log canonical at some point $Q \in G$.

Lemma 4.6. The threefold $W$ is smooth at the point $Q$.

Proof. Suppose that $W$ is singular at the point $Q$. Then $Q$ is a singular point of type $\frac{1}{r}(1, 1, r - 1)$, where either $r = r - a$, or $r = \bar{a} \neq 1$. Let $\omega: \hat{W} \rightarrow W$ be a blow up of $Q$ with weights $(1, 1, r - 1)$, and $\mathcal{H}$ be the proper transform of $\mathcal{P}$ on $\hat{W}$. Then it follows from \cite{3} that $\mathcal{H} \equiv -nK_{\hat{W}}$, which implies that $n = r\mu = a_1$ due to \cite{1}. However we know that $\mu > n/r$. \qed

Thus, it follows from Lemma \cite{4.6} that $\text{mult}_Q(\bar{D}) > n - ne - (\mu - n/r)\text{mult}_Q(\bar{E}).$

Lemma 4.7. There is a surface $T \in | - K_W |$ such that $Q \in T$.

Proof. The existence of a surface $T \in | - K_W |$ that passes through the point $Q$ is obvious in the case when $a_1 = 1$. Thus, we may assume that $a_1 \neq 1$. Then $\mathfrak{I} \in \{33, 38, 58\}$, but we consider only the case $\mathfrak{I} = 38$, because the cases $\mathfrak{I} = 33$ and $\mathfrak{I} = 58$ can be considered in a similar way.

Suppose that $\mathfrak{I} = 38$. Then there is a unique surface $T \in | - K_W |$. Suppose that $Q \not\in T$.

Arguing as in the proof of Lemma \cite{2.1} we see that $\text{mult}_Q(\bar{D}) \leq (a_1 + a_2)/a_1$. Then

$$\frac{\nu a_1 + a_2}{a_1} > n - (\mu - n/7) - (\nu + 3\mu/5 - 2n/7),$$

but $\text{mult}_Q(\bar{D}) > n + n/r - \mu - ne$. Thus, we have $\mu > 55n/56 - 5n/2$. The inequality $-K_W \cdot D \geq 0$ and the proof of Lemma \cite{2.3} imply that $\nu \leq 10\mu/7$ and $\mu \leq 9n/40$, respectively. The hypersurface $X$ can be given by the equation

$$w^2y + w(t^2 + tf_5(x, y, z) + f_{10}(x, y, z)) + tf_{13}(x, y, z) + tf_{18}(x, y, z) = 0 \subset \text{Proj}(\mathbb{C}[x, y, z, t, w]),$$

where $w^2y + w(t^2 + tf_5(x, y, z) + f_{10}(x, y, z)) + tf_{13}(x, y, z) + tf_{18}(x, y, z) = 0 \subset \text{Proj}(\mathbb{C}[x, y, z, t, w])$. 

where \(\text{wt}(x) = 1, \text{wt}(y) = 2, \text{wt}(z) = 3, \text{wt}(t) = 5, \text{wt}(w) = 8\), and \(f_i(x, y, z)\) is a quasihomogeneous polynomial of degree \(i\). Let \(\tilde{S}\) be the proper transform on the threefold \(W\) of the surface that is cut out on \(X\) by the equation \(wy + (t^2 + tf_5(x, y, z) + f_10(x, y, z)) = 0\). Then

\[
\tilde{S} \equiv (\alpha \circ \beta)^*( -10K_X) - \frac{18}{8}\beta^*(E) - \frac{13}{5}G,
\]

but \(\tilde{S} \neq \tilde{D}\). The divisor \(-K_W\) is nef. Hence, we have

\[
0 \leq -K_W \cdot \tilde{D} \cdot \tilde{S} = 3n/4 - 6\mu/5 - 13\nu/6,
\]

but \(\nu \leq 8\mu/5\), which implies \(\nu \leq 9n/35\). Now we can easily obtain a contradiction. \(\square\)

It follows from \([2]\) that \(|-rK_W|\) does not have base points for \(r \gg 0\) and induces a birational morphism \(\omega: W \rightarrow \tilde{W}\) such that \(\tilde{W}\) is a hypersurface in \(\mathbb{P}(1, a_1, a_2, 2a_3, 3a_3)\) of degree \(6a_3\)

**Lemma 4.8.** The morphism \(\omega\) is not an isomorphism in a neighborhood of the point \(Q\).

**Proof.** Suppose that \(\omega\) is an isomorphism in a neighborhood of the point \(Q\). Then it follows from the proof of Theorem 5.6.2 in \([5]\) that there is \(R \in |-s2a_1a_3K_W|\) such that \(\text{mult}_Q(R) \geq s\), but \(R\) does not contain components of the cycle \(\tilde{D} \cdot S\) that pass through \(Q\), where \(s \in \mathbb{N}\). Then

\[
s2a_3(-n/a_1K^3_X - \mu/a_3 - \nu/a_2) = R \cdot \tilde{D} \cdot T \geq \text{mult}_Q(\tilde{D} \cdot T)s > (n - \nu - (a_3 - a_1)/a_3 + 2n/a_4)s,
\]

because \(Q \notin \tilde{E}\). Now we can derive a contradiction using \(ne = \nu + (a_3 - a_1)/a_3 - 2n/a_4 > 0\). \(\square\)

It follows from Lemma 4.8 that there is a unique curve \(C \subset W\) that contains \(Q\) such that

\[-K_W \cdot C = 0, \beta^*(-K_D) \cdot C = 1/a_4, C \cdot G = 1,
\]

which implies that \(J \notin \{33, 38, 58\}\) by Lemma 4.7. Hence, we have \(J \in \{12, 13, 20, 25, 31\}\).

Put \(\tilde{D} \cdot T = mC + \Omega\), where \(m\) is a non-negative integer, and \(\Omega\) is an effective one-cycle, whose support does not contain the curve \(C\). Then it follows from Remark 2.12 that

\[
m \leq 5n/4 - \mu, m \leq 11n/15 - \mu/2, m \leq 13n/15 - \mu, m \leq 5n/7 - \mu/3, m \leq 2n/3 - \mu
\]

in the case when \(J = 12, 13, 20, 25, 31\), respectively. Recall that \(G\) is a section of \(\eta\).

Let \(H\) be a pencil in \(|-a_2K_W|\) of surfaces passing through the point \(Q\), and \(H\) be a general surface in \(\mathcal{H}\). Then \(C\) is the only curve in the base locus of \(\mathcal{H}\) that passes through \(Q\). Then

\[
-na_2K^3_X - a_2\mu/(a_1a_3) - \nu/a_1 = H \cdot \Omega \geq \text{mult}_Q(\Omega) > n - \nu - (a_3 - a_1)/a_3 + 2n/a_4 - m,
\]

which immediately implies that either \(J = 12\), or \(J = 13\).

**Lemma 4.9.** The inequality \(J \neq 12\) holds.

**Proof.** Suppose that \(J = 12\). Let \(R\) be a sufficiently general surface in \(|-2K_W|\) that contains the point \(Q\). Then \(R|_T = C + L + Z\), where \(L = G|_T\), the curve \(Z\) is reduced, and \(P \notin \beta(Z)\).

Suppose that \(Z\) is irreducible. Then \(Z^2 = -4/3, C^2 = -2, L^2 = -3/2\) on the surface \(T\). Put

\[
\tilde{D}|_T = mC + mL + mZ + \Upsilon,
\]

where \(m_C, m_L\) and \(m_Z\) are non-negative integers, and \(\Upsilon\) is an effective one-cycle, whose support does not contain the curve \(C, L\) and \(Z\).

Suppose that \(Q \notin \tilde{E}\). Then \(m_C > 2n/3 - m_Z/3\), because

\[
5n/6 - 2\mu/3 - \nu = R \cdot \tilde{D} \cdot T = mL + mZ/3 + R \cdot \Upsilon > mL + mZ/3 + 3n/2 - 2\mu/3 - m_L - m_C,
\]

but \(4m_Z/3 \geq 2m_C - n/3\), because \(\Upsilon \cdot Z \geq 0\). Thus, we have

\[
m_C > 2n/3 + m_Z/3 \geq 7n/12 + m_C/2,
\]

which gives \(m_C > 7n/6\), but \(m_C \leq 5n/6\) by Remark 2.12 because \(-K_X \cdot \alpha \circ \beta(C) = 5/6\).

Thus, we see that \(Q \in \tilde{E}\). Then \(C \subset \tilde{E}\) and \(\beta(C) \in |O_{P(1, 1, 3)}(1)|\), but

\[
5n/6 - 2\mu/3 - \nu = R \cdot \tilde{D} \cdot T = mL + mZ/3 + R \cdot \Upsilon > mL + mZ/3 + 7n/4 - \nu - 5\mu/3 - m_L - m_C,
\]

which gives \(m_C > 11n/12 - \mu + m_Z/3\). We have \(-K_X \cdot \alpha \circ \beta(Z) = 5/6\) and \(Z \cdot \tilde{E} = 2\), but

\[
4m_Z/3 \geq 2m_C + 2\mu - 5n/6,
\]

because \(Z \cdot \Upsilon \geq 0\). Thus, we have \(m_Z > 3n/2\), but \(m_Z \leq n/2\) by Remark 2.12.
Therefore, the curve $Z$ is reducible. Then $Q \in \mathcal{E}$ and $Z = \mathcal{Z} + \mathcal{Z}$, where $\mathcal{Z}$ and $\mathcal{Z}$ are irreducible curves such that $G \cdot \mathcal{Z} = G \cdot \mathcal{Z} = -(K_X + \beta (\mathcal{Z})) = 0$ and $-K_X \cdot \alpha \circ \beta (\mathcal{Z}) = 7/12$. Then $\mathcal{Z}^2 = -4/3$, $\mathcal{Z}^2 = C^2 = -2$, $L \cdot C = \mathcal{Z} \cdot C = \mathcal{Z} \cdot \mathcal{Z} = \mathcal{Z} \cdot \mathcal{Z} = 1$, $L \cdot \mathcal{Z} = L \cdot \mathcal{Z} = 0$ on the surface $T$. Put $D|_T = \bar{m}_C C + \bar{m}_L L + \bar{m}_Z \mathcal{Z} + \Phi$, where $\bar{m}_C$, $\bar{m}_L$, $\bar{m}_Z$ are non-negative integers, and $\Phi$ is an effective cycle, whose support does not contain $C$, $L$ and $\mathcal{Z}$. Then 

$R|_T \cdot \Phi \geq \text{mult}_Q (\Phi) > 7n/4 - \nu - 5\mu/3 - mL - mC,$

and $\Phi \cdot \mathcal{Z} \geq 0$. We have $\beta^* (-K_U)|_T \cdot \Phi \geq 0$. Thus, we see that $\bar{m}_C > 11n/12 - \mu + \bar{m}_Z/3$, $4\bar{m}_Z/3 \geq \bar{m}_C + (\mu - 5n/6)$, $\bar{m}_C + \mu \leq 5/4 - \bar{m}_Z$, but this system of linear inequalities is inconsistent, which completes the proof. □

Thus, we see that $\mathcal{J} = 13$. Then $C \subset \mathcal{E}$, because otherwise we have $2(11n/30 - \mu/6 - \nu/2) = H \cdot \Omega \geq \text{mult}_Q (\Omega) > 7n/5 - \nu - \mu/3 - m$, which implies that $m > 2n/3$, which is impossible, because $m \leq 11n/15 - \mu/2$ and $\mu > n/5$. Put $D|_E = \bar{m} C + \Upsilon$, where $\bar{m}$ is a non-negative integer, and $\Upsilon$ is an effective cycle, whose support does not contain the curve $C$. Then $\bar{m} \leq 5\mu/2$, because we have $\beta (C) \in |O_{\mathcal{P}(1, 2, 3)}(2)|$ and the curve $C$ is reduced, where $E \equiv \mathcal{P}(1, 2, 3)$. Then $\bar{m} \leq 11n/12$, because $\mu \leq 11n/30$.

The log pair $(W, \frac{1}{\pi} D + \bar{E} + \epsilon G)$ is not log canonical at the point $Q$. Hence, the log pair 

$\left(\mathcal{E}, C + \frac{\nu + \mu/3 - 2n/5}{n} G|_E + \frac{1}{n} \Upsilon\right)$

is not log canonical at the point $Q$ by Theorem 7.5 in [9]. Then $5\mu/3 - \nu = (\bar{m} C + \Upsilon) \cdot C = \Upsilon \cdot C > 7n/5 - \nu - \mu/3$, because $\text{mult}_Q (\Upsilon|_C) > 7n/5 - \nu - \mu/3$ by Theorem 7.5 in [9]. Thus, we see that $\mu > 7n/10$, which is impossible, because $\mu \leq 11n/30 < 7n/10$. The assertion of Lemma 2.11 is proved.

5. QUADRATIC INVOLVATIONS.

In this section we prove the assertion of Lemma 2.11. Let us use the assumptions and notation of Lemma 2.11. Suppose that $d = 2r + a_j$. To prove Lemma 2.11 we must derive a contradiction. It follows from the equality $d = 2r + a_j$ that the threefold $X$ can be given by the equation

$x_i^2 x_j + x_i f(x_0, x_1, x_2, x_3, x_4) + g(x_0, x_1, x_2, x_3, x_4) = 0 \subset \text{Proj} \left(C[x_0, x_1, x_2, x_3, x_4]\right),$

where $i \neq j$, $a_i = r$, $\text{wt}(x_0) = 1$, $\text{wt}(x_k) = a_k$, $f$ and $g$ are quasihomogeneous polynomials that do not depend on $x_i$. Put $\bar{a}_3 = a_{3+4-i}$, $\bar{a}_4 = a_i a_j$, $\bar{d} = 2\bar{a}_4$. Then there is a commutative diagram

$$
\begin{array}{ccc}
U & \xrightarrow{\alpha} & X \\
\sigma \downarrow & & \downarrow \xi \\
V & \xrightarrow{\chi} & \mathbb{P}(1, a_1, a_2, \bar{a}_3, \bar{a}_4)
\end{array}
$$

where $\xi$ and $\chi$ are projections, and $\sigma$ is a birational morphism that contracts smooth irreducible rational curves $C_1, \ldots, C_l$ such that $V$ is a hypersurface in $\mathbb{P}(1, a_1, a_2, \bar{a}_3, \bar{a}_4)$ of degree $\bar{d}$ with terminal non-$Q$-factorial singularities, where $l = a_i a_j (d - a_j) \sum_{i=1}^{3} a_i$. Then $-K_X \cdot \alpha (C_k) = 1/a_i$.

Let $M$ be the surface that is cut out on the threefold $X$ by $x_j = 0$, and $M$ be the proper transform of $M$ on the threefold $U$. Then $M \neq D$ by Lemma 8.12 and Proposition 8.14 in [9].

**Lemma 5.1.** The inequalities $\mu \leq -a_j n K_X^3 (r - a)/{(d - r)} \leq n (d - r)/(ra_j)$ hold.

**Proof.** The divisor $-K_U$ is nef. The inequality $\mu \leq -a_j n K_X^3 (r - a)/{(d - r)}$ follows from

$0 \leq -K_U \cdot M \cdot D = -a_j n K_X^3 - \mu (d - r)/(ar - a^2),$

and to conclude the proof we must show that $-a_j n K_X^3 (r - a)/{(d - r)} \leq n (d - r)/(ra_j)$. 
Suppose that \(-a_jnK_X^2(r-a)/d(r) > n(d-r)/(ra_j)\). Then
\[
\frac{d-r}{ra_j} < -a_jK_X^2(r-a)a \frac{d}{d(r)} = \frac{da_j(r-a)a}{(d-r)a_1a_2a_3a_4},
\]
but \(a_1a_2a_3a_4 \geq a_jr(r-a)a\). Thus, we have \((d-r)^2 < d(2dr)\), which is a contradiction. \(\square\)

We have \(E \cong \mathbb{P}(1,a,r-a)\), and \(|\mathbb{O}_{\mathbb{P}(1,a,r-a)}(1)|\) consists of a single curve when \(a \neq 1\).

**Lemma 5.2.** The inequality \(a \neq 1\) holds.

**Proof.** Suppose that \(a = 1\). Taking into account the possible values of \((a_1, a_2, a_3, a_4)\), we see that
\[
\mathcal{I} \in \left\{6, 7, 8, 9, 12, 13, 16, 17, 20, 25, 26, 30, 36, 31, 41, 47, 54\right\},
\]
but we only consider the cases \(\mathcal{I} = 7\) and \(\mathcal{I} = 36\). The remaining 16 cases can be considered in a similar way. So the reader can easily obtain a contradiction in these cases by himself.

Suppose that \(\mathcal{I} = 7\). Then \(X\) is a hypersurface in \(\mathbb{P}(1, 1, 2, 2, 3)\) of degree 8, which implies that the point \(O\) is a singular point of \(\frac{1}{2}(1, 1, 2)\). Let \(S\) be the unique surface in \(|\mathcal{J}| - K_U\) that contains the point \(P\). Then \(S\) is an irreducible surface, which is smooth at the point \(P\).

The singularities of \(U\) consists of singular points \(P_0, P_1, P_2, P_3, P_4\) of type \(\frac{1}{2}(1, 1, 1)\) such that \(P_0\) is a singular point of \(E\). It follows from [2] that there is a commutative diagram

\[
\begin{array}{ccc}
U & \xrightarrow{\beta_i} & Y_i \\
\downarrow{\alpha} & & \downarrow{\eta_i} \\
X & \xrightarrow{\xi_i} & \mathbb{P}(1, 1, 2),
\end{array}
\]

where \(\xi_i\) is a projection, \(\beta_i\) is a blow of \(P_i\) with weights \((1, 1, 1)\), and \(\eta_i\) is a morphism.

Suppose that \(P \not\in \bigcup_{i=1}^{5} C_i\). The proper transform of \(E\) on the threefold \(Y_i\) is a section of \(\eta_i\) in the case when \(i \neq 0\). Hence, there is a surface \(H \in |\mathcal{J}|\) such that
\[
2(2n/3 - \mu/2) = \frac{D}{\cdot} \cdot H \cdot S \geq \text{mult}_P(\mathcal{D}) > 4n/3 - \mu,
\]
which is a contradiction. So we may assume that \(P \in C_1\). Then \(-K_X \cdot a(C_1) = 1/3\).

Let \(Z_1\) be an irreducible curve such that \(\mathcal{M}|_S = C_1 + Z_1\). Put \(L = E|_S\). Then
\[
C_1^2 = -2, \quad Z_1^2 = L^2 = -3/2, \quad C_1 \cdot Z_1 = L \cdot C_1 = 1, \quad L \cdot Z_1 = 3/2
\]
on the surface \(S\). Put \(\mathcal{D}|_S = mC_1 + mZ_1 + mL + \Omega\), where \(mC_1, mZ_1\) and \(mL\) are non-negative integers, and \(\Omega\) is an effective cycle, whose support does not contain \(C_1, Z_1\) and \(L\). Then
\[
n - 3\mu/2 + 3mZ_2/2 - 3mL/2 - mC_1 = Z_1 \cdot \Omega \geq 0, \quad 3\mu/2 - 3mZ_2/2 + 3mL/2 - mC_1 = L \cdot \Omega \geq 0,
\]
which implies that \(3mZ_2/2 \geq 3(\mu + mL)/2 + mc_1 - n\) and \(3(\mu + mL)/2 \geq 3mZ_2/2 + mC_1\). Then
\[
4n/3 - \mu - mL - mZ_2 = (L + C_1 + Z_1) \cdot \Omega \geq \text{mult}_P(\Omega) > 4n/3 - \mu - mL - mC_1,
\]
which gives \(mC_1 > mZ_2\) and \(4n/3 \geq (\mu + mL + mZ_2)\). So we see that \(mZ_2 \leq n/2\) and \(mC_1 \leq n/2\).

Then it follows from Theorem 7.5 in [9] that the log pair
\[
(S, C_1 + \frac{\frac{mL}{n} + \frac{mZ}{n}}{\Omega} + \frac{1}{n} \Omega)
\]
is not log canonical at \(P\), because \(mC_1 \leq n\). So it follows from Theorem 7.5 in [9] that
\[
C_1 \cdot \Omega \geq \text{mult}_P(\Omega|_C_1) > n - mL - m + n/3,
\]
which implies that \(mC_1 > mZ_2/2 + n/2\), but \(mC_1 \leq n/2\). So the case \(\mathcal{I} = 7\) is impossible.

Now we suppose that \(\mathcal{I} = 36\). Then \(X\) is a general hypersurface in \(\mathbb{P}(1, 1, 4, 6, 7)\) of degree 18, and \(O\) is a singular point of \(\frac{1}{4}(1, 1, 6)\). Arguing as in the case \(\mathcal{I} = 7\), we see that \(P \not\in \bigcup_{i=1}^{7} C_i\), which implies that we may assume that \(P \in C_1\). Put \(L = C_1\).

Let \(S\) be a surface in \(|\mathcal{J}|\) such that \(P \in S\). Then \(\mathcal{M}|_S = L + Z\), where \(Z\) is an irreducible curve. Put \(C = E|_S\). Then the intersection form of \(C, L, Z\) on \(S\) is given by
\[
Z^2 = C^2 = -7/6, \quad L^2 = -2, \quad Z \cdot L = C \cdot L = 1, \quad Z \cdot C = 5/6,
\]
and $P$ is the intersection point of the curves $L$ and $C$. Put
\[ D|_S = mL + mC + mZ + \Omega, \]
where $m_L$, $m_C$ and $m_Z$ are non-negative integers, and $\Omega$ is an effective cycle, whose support does not contain the curves $L$, $C$, and $Z$.

It follows from the proof of Theorem 5.6.2 in \cite{5} that we can find $H \in |-s6K_U|$ that has multiplicity at least $s > 0$ at the point $P$, but does not contain components of $\Omega$ that pass through the point $P$, where $s$ is a natural number. Then
\[ s6(3n/28 - \mu/6 - mC/6 - mZ/6) = H|_S \cdot \Omega \geq \text{mult}_P(\Omega)s > (8n/7 - \mu - mL - mC)s, \]
which implies that $m_L > n/2 + m_Z$, but $m_L \leq 3n/4$ by Remark 2.12. We have
\[ 3n/28 - \mu/6 = -K_U|_S \cdot (m_L + mC + mZ + \Omega) \geq -K_U|_S \cdot (m_L + mC + mZ) = \frac{mC + mZ}{6}, \]
which implies that $m_C + m_Z < 9n/14 - \mu$. On the surface $S$, we have
\[ 7\mu/6 + 7mC/6 - 5mZ/6 - m_L = \Omega \cdot C > 8n/7 - \mu - m_L - m_C, \]
which implies that $13(\mu + m_C)/6 > 8n/7 + 5m_Z/6$. The inequality $\Omega \cdot Z \geq 0$ implies that
\[ 3n/4 \geq m_L > n/2 + m_Z, \]
which implies that $7m_Z/6 > 5\mu/6 + m_L + 5mC/6 - 2n/7$, but $m_Z \leq 3n/8$ by Remark 2.12.

It follows from Lemma 5.1 that $18n/77 > \mu > n/7$. The inequalities obtained
\[
\begin{cases}
13(\mu + m_C)/6 > 8n/7 + 5m_Z/6, \\
21n/48 \geq 7m_Z/6 \geq 5\mu/6 + m_L + 5m_C/6 - 2n/7, \\
m_C + m_Z < 9n/14 - \mu, \\
3n/4 \geq m_L > n/2 + m_Z, \\
18n/77 \geq \mu > n/7,
\end{cases}
\]
are inconsistent. So we have a contradiction. Thus, the case $\mathcal{J} = 36$ is impossible as well.

Taking into account the possible values of the quadruple $(a_1, a_2, a_3, a_4)$, we see that $\mathcal{J} \in \{13, 18, 23, 24, 27, 32, 38, 40, 42, 43, 44, 45, 46, 48, 56, 58, 60, 61, 65, 68, 69, 74, 76, 79\}$ by Lemma 5.2.

**Lemma 5.3.** The point $P$ is contained in the surface $T$.

**Proof.** It follows from Lemmas 2.13 and 5.1 that $P \in T$ unless $\mathcal{J} \in \{13, 24\}$. Therefore, we may assume that $\mathcal{J} \in \{13, 24\}$ and $P \notin T$. Let us derive a contradiction.

Let $L$ be the curve in $|O_{\mathbb{P}(1,a,r-a)}(1)|$. Then $P \notin L$, because $P \notin T$. Thus, there is a unique smooth irreducible curve $C$ in the linear system $|O_{\mathbb{P}(1,a,r-a)}(a)|$ that contains the point $P$. Put $D|_E = \delta C + \Upsilon \equiv r \mu L,$ where $\delta$ is a non-negative integer, and $\Upsilon$ is an effective cycle such that $C \not\subset \text{Supp}(\Upsilon)$.

Arguing as in the proof of Lemma 2.13, we see that $\delta \leq r \mu/a$, which gives $\delta < n$ by Lemma 5.1.

It follows from Theorem 7.5 in \cite{9} that $(E, \frac{1}{n}D|_E)$ is not log canonical at $P$, which implies that the log pair $(E, C + \frac{1}{n}T)$ is not log canonical at $P$. It follows from Theorem 7.5 in \cite{9} that
\[ r\mu/(r-a) \geq (r\mu - a\delta)/(r-a) = C \cdot \Upsilon \geq \text{mult}_P(\Upsilon|_C) > n, \]
which implies that $\mu \geq n(r-a)/r$, which is impossible by Lemma 5.1.

It follows from \cite{5} that $T \cap E \cap \bigcup_{i=1}^n C_i \neq \emptyset \iff \mathcal{J} \in \{43, 46, 69, 74, 76, 79\}$.

**Lemma 5.4.** The case $\mathcal{J} \notin \{13, 24, 32, 43, 46\}$ is impossible.

**Proof.** Suppose that $\mathcal{J} \notin \{13, 24, 32, 43, 46\}$. It follows from the proof of Theorem 5.6.2 in \cite{5} that there are $s \in \mathbb{N}$ and $H \in |-s\alpha_3K_U|$ such that $\text{mult}_P(H) \geq s$, but $H$ does not contain components of the cycle $D \cdot T$ passing through $P$ that are different from the curves $C_1, \ldots, C_i$.

We have $\mathcal{J} \in \{69, 74, 76, 79\}$ and $P \in \bigcup_{i=1}^n C_i$, because otherwise we get a contradiction using
\[ s\alpha_3 \left(-nK_X^\lambda - \frac{\mu}{a(r-a)}\right) = D \cdot H \cdot T \geq \text{mult}_P(D)s > (n + n/r - \mu)s. \]
We may assume that $P \in C_1$. Put $D \cdot T = mC_1 + \Delta$, where $m$ is a non-negative integer number, and $\Delta$ is an effective cycle, whose support does not contain the curve $C_1$. Then it follows from the proof of Theorem 5.6.2 in [5] that there is a surface $R = -sa_1 \bar{a}_3 K_U$ such that
\[ sa_1 \bar{a}_3 \left( -nK_X^3 - \frac{\mu}{a(r - a)} \right) = R \cdot \Delta \geq \text{mult}_P(\Delta) s > (n + n/r - \mu - m)s, \]
where $s \in \mathbb{N}$. The inequality obtained is impossible, because $m \leq -a_i nK_X^3$ by Remark 2.12.

Suppose that $\mathfrak{I} = 56$. As in the previous case, there is $H \in |-s24K_U|$ such that
\[ s24(n/22 - \mu/24) = D \cdot H \cdot T \geq \text{mult}_P(\bar{D}) s > (12n/11 - \mu)s, \]
where $s$ is a natural number. Now we can easily obtain a contradiction with $\mu > n/r$. \hfill $\square$

Thus, to complete the proof of Lemma 2.11 we have to consider the cases $\mathfrak{I} = 13, 24, 32, 43, 46$ one by one. For the sake of simplicity, we only consider the cases $\mathfrak{I} = 13$ and $\mathfrak{I} = 43$, because the remaining cases can be considered in a similar way.

**Lemma 5.5.** The inequality $\mathfrak{I} \neq 43$ holds.

**Proof.** Suppose that $\mathfrak{I} = 43$. Then $X$ is a general hypersurface in $\mathbb{P}(1, 2, 3, 5, 9)$ of degree 20, and $O$ is a singular point of type $\frac{5}{2}(1, 4, 5)$. The base locus of $|-2K_U|$ consists of two reducible curves $C$ and $L$ such that $L = T \cdot E$, and $C$ is the curve among $C_1, \ldots, C_t$ such that $C \cap L \neq \emptyset$.

Suppose that $P \notin C$. Then it follows from the proof of Theorem 5.6.2 in [5] that we can find a surface $H \in |-s20K_U|$ that has multiplicity at least $s > 0$ at the point $P$ and does not contain components of $D \cdot T$ that pass through $P$, where $s$ is a natural number. Then
\[ s20(n/18 - \mu/20) = D \cdot H \cdot T \geq \text{mult}_P(\bar{D}) s > (10n/9 - \mu)s, \]
which implies that $\mu < n/9$, but $\mu > n/10$.

We see that $P \in C$. Then $\bar{M}$ contains $C$ and $L$. Put
\[ \bar{D}|_{\bar{M}} = m_1L + m_2C + \Delta, \]
where $m_1$ and $m_2$ are non-negative integers, and $\Delta$ is an effective cycle, whose support does not contain $L$ and $C$. Then $m_2 \leq n$ by Remark 2.12 because $\alpha^*(K_X) \cdot C = 1/9$.

The surface $\bar{M}$ is smooth at $P$. So it follows from Theorem 7.5 in [9] that the log pair
\[ \left( \bar{M}, \frac{1}{n} \bar{D}|_{\bar{M}} + (\mu/n - 1/9) E|_{\bar{M}} \right) \]
is not log canonical in a neighborhood of the point $P$, but $E|_{\bar{M}} = L + Z$, where $Z$ is an irreducible curve that does not pass through the point $P$. Therefore, the singularities of the log pair
\[ \left( \bar{M}, \left( m_1/n + \mu/n - 1/9 \right) L + C + \frac{1}{n} \Delta \right) \]
are not log canonical at the point $P$. So it follows from Theorem 7.5 in [9] that
\[ n/9 - \mu - m_1 + m_2 = \Delta \cdot C \geq \text{mult}_P(\Delta|C) > n - m_1 - \mu + n/9, \]
because $C^2 = -1$ and $C \cdot L = 1$ on $\bar{M}$. Thus, we have $m_2 > n$, which is a contradiction. \hfill $\square$

Suppose that $\mathfrak{I} = 13$. Then $r = 5$ by Lemma 5.2. The base locus of the pencil $|-K_U|$ consists of two curves $C$ and $L$ such that $C = E|_T$, and $\alpha(L)$ is the base curve of $|-K_X|$. Then
\[ \bar{C}^2 = \bar{L}^2 = -5/6, \quad \bar{L} \cdot \bar{C} = 1 \]
on the surface $T$. Put $D|_T = \bar{m}_L \bar{L} + \bar{m}_C \bar{C} + \bar{\Upsilon}$, where $\bar{m}_L$ and $\bar{m}_C$ are non-negative integers, and $\bar{\Upsilon}$ is an effective cycle, whose support does not contain $\bar{L}$ and $\bar{C}$. Then
\[ 11n/5 - 11\mu/6 = \left( 6L + 5C \right) \cdot \left( \bar{m}_L \bar{L} + \bar{m}_C \bar{C} + \bar{\Upsilon} \right) = 11\bar{m}_C/6 + (6L + 5C) \cdot \bar{\Upsilon} \geq 11\bar{m}_C/6, \]
which implies that $\bar{m}_C \leq 6n/5 - \mu$. Thus, we have $\bar{m}_C < n$, because $\mu > n/5$.

Suppose that $P \notin \bar{L}$. Then it follows from Theorem 7.5 in [9] that the log pair
\[ \left( S, \bar{C} + \frac{\bar{m}_L}{n} L + \frac{1}{n} \bar{\Upsilon} \right) \]
is not log canonical in the neighborhood of the point $P$, because $\bar{m}_C + \mu - n/5 \leq n$, which implies that the inequality $\text{mult}_P(\bar{\Upsilon}|_{\bar{C}}) > n$ holds by Theorem 7.5 in [9]. Hence, we have
\[ 5\mu/6 + 5\bar{m}_C/6 \geq 5\mu/6 - \bar{m}_L + 5\bar{m}_C/6 = \bar{\Upsilon} \cdot \bar{C} > n, \]
which is impossible, because \( \bar{m}_C \leq 6/5 - \mu \). Thus, we see that \( P = \bar{L} \cap \bar{C} \).

Put \( \overline{D}_M = mL + \Omega \), where \( m \) is a non-negative integer, and \( \Omega \) is an effective cycle, whose support does not contain \( \bar{L} \). Then \( L^2 = 1/6 \) on the surface \( \overline{M} \). But \( m \leq n \) by Remark 2.12.

Arguing as in the case \( P \notin \bar{L} \) we see that \( \text{mult}_P(\Omega|_L) > n \) by Theorem 7.5 in [9], and

\[
11n/30 - \mu = \overline{D} \cdot \bar{L} = m/6 + \Omega \cdot \bar{L} > m/6 + n,
\]

which implies that \( m < 0 \). So we have a contradiction, which completes the proof of Lemma 2.11.

### 6. Direct products.

Let \( X \) be an arbitrary Fano variety with terminal \( \mathbb{Q} \)-factorial singularities of Picard rank one, and \( \Gamma \) be a subgroup of the group \( \text{Bir}(X) \).

**Definition 6.1.** The subgroup \( \Gamma \subset \text{Bir}(X) \) untwists all maximal singularities if for every linear system \( \mathcal{M} \) on the variety \( X \) that has no fixed components there is \( \xi \in \Gamma \) such that the singularities of the log pair \((X, \lambda \xi(\mathcal{M}))\) are canonical, where \( \lambda \in \mathbb{Q} \) such that \( K_X + \lambda \xi(\mathcal{M}) \equiv 0 \).

It is well known that the group \( \text{Bir}(X) \) is generated by the subgroups \( \Gamma \) and \( \text{Aut}(X) \) in the case when the subgroup \( \Gamma \) untwists all maximal singularities (see [1]).

**Definition 6.2.** The variety \( X \) is birationally superrigid\(^4\) (rigid, respectively) if the trivial subgroup (the whole group \( \text{Bir}(X) \), respectively) untwists all maximal singularities.

The birational rigidity of \( X \) implies that there is no dominant rational map \( \rho: X \to Y \) such that \( \dim(Y) \geq 1 \), and sufficiently general fiber of the map \( \rho \) is rationally connected (see [1]).

**Example 6.3.** It follows from [12] that the variety \( X \) is birationally superrigid and \( \text{lct}(X) = 1 \) in the case when \( X \) is one of the following smooth Fano varieties:

- a general hypersurface in \( \mathbb{P}^r \) of degree \( r \geq 6 \);
- a general hypersurface in \( \mathbb{P}(1^{m+1}, m) \) of degree \( 2m \geq 6 \).

**Definition 6.4.** The subgroup \( \Gamma \) universally untwists all maximal singularities if for every variety \( U \), and every linear system \( \mathcal{M} \) on the variety \( X \times U \) that does not have fixed components, there is a birational automorphism \( \xi \in \Gamma \) such that the log pair

\[
\left( F, \frac{\lambda \xi(\mathcal{M})}{F} \right)
\]

has at most canonical singularities, where \( F \) is a sufficiently general fiber of the natural projection \( X \times U \to U \), and \( \lambda \) is a positive rational number such that \( K_F + \lambda \xi(\mathcal{M})|_F \equiv 0 \).

Let \( X_1, \ldots, X_r \) be Fano varieties of Picard rank one with terminal \( \mathbb{Q} \)-factorial singularities. Put

\[
U_i = X_1 \times \cdots \times X_{i-1} \times \hat{X}_i \times X_{i+1} \times \cdots \times X_r
\]

and \( V = X_1 \times \cdots \times X_r \). Let \( \pi_i: V \to U_i \) be a natural projection.

For every \( i \in \{1, \ldots, r\} \), suppose that \( \text{lct}(X_i) \geq 1 \), and there is a subgroup \( \Gamma_i \subset \text{Bir}(X_i) \) that universally untwists all maximal singularities. Then the following result holds.\(^5\)

**Theorem 6.5.** The variety \( X_1 \times \cdots \times X_r \) is non-rational, and

\[
\text{Bir}\left(X_1 \times \cdots \times X_r\right) = \left\langle \prod_{i=1}^r \Gamma_i, \text{Aut}\left(X_1 \times \cdots \times X_r\right) \right\rangle,
\]

for any dominant rational map \( \rho: X_1 \times \cdots \times X_r \to Y \) whose general fiber is rationally connected, there is a commutative diagram

\[
\begin{array}{ccc}
X_1 \times \cdots \times X_r & \xrightarrow{\sigma} & X_1 \times \cdots \times X_r \\
\pi \downarrow & & \downarrow \rho \\
X_{i_1} \times \cdots \times X_{i_k} & \xrightarrow{\xi} & Y
\end{array}
\]

where \( \xi \) and \( \sigma \) are birational maps, and \( \pi \) is a projection for some \( \{i_1, \ldots, i_k\} \subseteq \{1, \ldots, r\} \).

It is well known that Theorem 6.5 is implied by the following technical result (see [12]).

\(^4\)There are several similar definitions of birational superrigidity and birational rigidity (see [5], [1]).

\(^5\)The assertion of Theorem 6.5 is proved in [12] for smooth birationally superrigid Fano varieties.
Proposition 6.6. For every linear system \( \mathcal{M} \) on the variety \( V \) such that
- the linear system \( \mathcal{M} \) does not have fixed components,
- the linear system \( \mathcal{M} \) does not lie in the fibers of the projections \( \pi_1, \ldots, \pi_r \),
there are \( k \in \{1, \ldots, r\} \), birational map \( \xi \in \prod_{i=1}^r \Gamma_i \) and a positive rational number \( \mu \) such that
  - the inequality \( \kappa(V, \mu \xi(\mathcal{M})) \geq 0 \) holds
  - the equivalence \( K_V + \mu \xi(\mathcal{M}) \equiv \pi_k^* (D) \) holds for some nef \( \mathbb{Q} \)-divisor \( D \) on \( U_k \).

Proof. Let \( F_i \) be a sufficiently general fiber of \( \pi_i \). The subgroups \( \Gamma_1, \ldots, \Gamma_r \) universally untwist all maximal singularities for every \( i = 1, \ldots, r \). So there is \( \xi \in \prod_{i=1}^r \Gamma_i \) such that the log pairs
\[
\left( F_1, \mu_1 \xi(\mathcal{M}) |_{F_1} \right), \ldots, \left( F_r, \mu_r \xi(\mathcal{M}) |_{F_r} \right)
\]
are canonical, where \( \mu_i \) is a rational number such that
\[
K_V + \mu_i \xi(\mathcal{M}) \equiv \pi_i^* (D_i),
\]
where \( D_i \) is a \( \mathbb{Q} \)-divisor on \( U_i \). Then there is \( m \in \{1, \ldots, r\} \) such that \( D_m \) is nef.

Now arguing as in the proof of Theorem 1 in [12], we see that \( \kappa(V, \mu_k \xi(\mathcal{M})) \geq 0 \). \( \square \)

Let \( X \) be a general quasismooth hypersurface in \( \mathbb{P}(1,a_1,a_2,a_3,a_4) \) of degree \( \sum_{i=1}^4 a_i \) with terminal singularities, where \( a_1 \leq a_2 \leq a_3 \leq a_4 \). Then \( X \) is a Fano threefold, whose divisor class group is generated by \(-K_X\). The possible values of \((a_1,a_2,a_3,a_4)\) are given in Table 5 in [7].

There are finitely many non-biregular birational involutions \( \tau_1, \ldots, \tau_k \in \text{Bir}(X) \) explicitly constructed in [5] such that the following result holds (see [5]).

Theorem 6.7. The subgroup \( \langle \tau_1, \ldots, \tau_k \rangle \) universally untwists all maximal singularities.

Example 6.8. Let \( X \) be a general hypersurface in \( \mathbb{P}(1,1,4,5,10) \) of degree 20, and \( U \) be a general hypersurface in \( \mathbb{P}(1^{n+1}, n) \) of degree \( 2n \geq 6 \). Then \( \text{Bir}(X \times U) \cong (\mathbb{Z}_2 \oplus \mathbb{Z}_2) \oplus \mathbb{Z}_2 \).

Example 6.9. Let \( X \) be a general hypersurface in \( \mathbb{P}(1,1,2,3,3) \) of degree 9, and \( U \) be a general hypersurface in \( \mathbb{P}^r \) of degree \( r \geq 6 \). Then
\[
\text{Bir}(X \times U) \cong \left\langle a, b, c \mid a^2 = b^2 = c^2 = (abc)^2 = 1 \right\rangle.
\]

It follows from [5] that \( \text{Aut}(X) \neq \text{Bir}(X) \) for exactly 45 values of \((a_1,a_2,a_3,a_4)\).
