Abstract

In this paper we undertake the error analysis of the time discretization of systems of Forward-Backward Stochastic Differential Equations (FBSDEs) with drivers having polynomial growth and that are also monotone in the state variable.

We show with a counter-example that the natural explicit Euler scheme may diverge, unlike in the canonical Lipschitz driver case. This is due to the lack of a certain stability property of the Euler scheme which is essential to obtain convergence. However, a thorough analysis of the family of $\theta$-schemes reveals that this required stability property can be recovered if the scheme is sufficiently implicit. As a by-product of our analysis we shed some light on higher order approximation schemes for FBSDEs under non-Lipschitz condition. We then return to fully explicit schemes and show that an appropriately tamed version of the explicit Euler scheme enjoys the required stability property and as a consequence converges.

In order to establish convergence of the several discretizations we extend the canonical path- and first order variational regularity results to FBSDEs with polynomial growth drivers which are also monotone. These results are of independent interest for the theory of FBSDEs.

Keywords : FBSDE, monotone driver, polynomial growth, time discretization, path regularity, Feynman-Kac formula, calculus of variations.

1 Introduction

There is currently a long literature on the numerical approximation of FBSDE with Lipschitz conditions ([BT04], [CM12], [GT14], [Cha12], [Cha13] and references within). In this article we address the case of FBSDEs with drivers having polynomial growth in the state variable, which has not been studied before, and provide customized analysis of various implicit and explicit schemes. The importance of FBSDEs with non-linear drivers is due to the fruitful connection between FBSDEs and partial differential equations (PDEs). Many biological and physical phenomena are modeled using PDEs of parabolic type, say for $(t,x) \in [0,T] \times \mathbb{R}^d$

\[-\partial_t v(t,x) - \mathcal{L} v(t,x) - f(t,x,v(t,x), (\nabla v \sigma)(t,x)) = 0, \quad v(0,x) = g(x),\]
with $\mathcal{L}$ a second order elliptic differential operator and certain measurable functions $f$ and $g$. A very large class of such equations can be linked to the solution process $\Theta^{t,x} = (X^{t,x}, Y^{t,x}, Z^{t,x})$ of certain forward-backward stochastic differential equations (FBSDE) with the following type of dynamics for $(t, x) \in [0, T] \times \mathbb{R}^d$, $s \in [t, T]$ and $W$ a Brownian-motion

$$
X^{t,x}_s = x + \int_t^s b(r, X^{t,x}_r)dr + \int_t^s \sigma(r, X^{t,x}_r)dW_r, 
$$

(1.1)

$$
Y^{t,x}_s = g(X^{t,x}_T) + \int_s^T f(r, \Theta^{t,x}_r)dr - \int_s^T Z^{t,x}_r dW_r,
$$

(1.2)

via the so called non-linear Feynman-Kac formula: $v(T - t, x) = Y^{t,x}_t$ (see e.g. [EKPQ97]).

In many applications of interest, like reaction-diffusion type equations, the function $f$ is a polynomial (in $v$), for example the Allen-Cahn equation, the FitzHugh-Nagumo equations (with or without recovery) or the standard non-linear heat and Schrödinger equation (see [Hen81], [Rot84], [ELW00], [Kov11] and references).

Motivated by these applications we look further at the connection between parabolic PDEs and FBSDEs with monotone drivers $f$ of polynomial growth (see [Par99], [BC00] and [BDHS03]). By monotonicity we mean that $\langle v' - v, f(v') - f(v) \rangle \leq \mu |v' - v|^2$, for some $\mu \geq 0$, and any $v, v'$ (one can also find the terminology that $f$ is 1-sided Lipschitz). We extend the above mentioned works by providing further regularity estimates for the FBSDE in question (modulus of continuity, path and variational regularity). Then, we proceed to a thorough analysis of various numerical methods that open the door to Monte Carlo methods for solving numerically the corresponding PDEs.

The applicability of the results we develop here is not restricted to the modeling of physical phenomena. It is also possible to extend the work we develop to the Brownian-Lévy setting and apply it for instance to problems of contingent claim hedging in defaultable markets, see e.g. instance [GLZ13].

The work and results we present should be understood as a first step in the numerical analysis of FBSDE with monotone drivers of polynomial growth, wider than the Lipschitz driver BSDE setting, with the intent of deepening the applicability of FBSDEs to reaction-diffusion equations. Moreover, we work without assuming knowledge on the density function or the moment generating function of the forward process $X$. In some applications where $X$ is simply the Brownian motion, it is possible to derive a numerical solver that takes advantage on this knowledge, see e.g. [ZGZ13]. The work we develop aims at black-box type algorithms which do not take advantage of any of the specific forms the FBSDE’s coefficients may take.

A motivating example

To better understand why the explicit Euler scheme seems not to be suitable for approximating the solution to BSDEs with non-Lipschitz drivers, let us consider the following simple example (for further details and notational setup see Section 2 and Appendix A.1)

$$
Y_t = \xi - \int_t^1 Y_s^3 ds - \int_t^1 Z_s dW_s, \quad t \in [0, 1]
$$

(1.3)

with the terminal condition $\xi \in F_1$. For any $\xi \in L^p$ for $p \geq 2$ there exists$^1$ a unique (square-integrable) solution $(Y, Z)$ to the above BSDE.

$^1$Existence and uniqueness follows from Section 2 in [Par99] or Theorem 2.2 below.
Fix the number of time-discretization points to be $N + 1 > 0$. The explicit Euler scheme for the above equation with uniform time step $h = 1/N$ is, with the notation $Y_i := Y_{i/N}$, given by

$$Y_i = E[Y_{i+1} - Y_{i+1}^3 h | F_i] = E[Y_{i+1}(1 - hY_{i+1}^2)] | F_i], \quad i = 0, \ldots, N - 1,$$

where $Y_N = \xi$.

It is a simple calculation (see Appendix A.1 for the details) to show that if

$$\xi \geq 2\sqrt{N} \quad \text{then} \quad |Y_i| \geq 2^{2N-i}\sqrt{N} \quad \text{for} \quad i = 0, \ldots, N.$$

With this simple computation in mind it is possible to show that there exists a random variable $\xi$ whose moments of any order are finite and for which the explicit Euler scheme diverges. The result below is a corollary of Lemma A.2 that can be found in Appendix A.1.

**Lemma 1.1.** Let $\pi^N$ be the uniform grid over the interval $[0,1]$ with $N + 1$ points, $N$ an even number ($t = 1/2$ is common to all grids $\pi^N$). For any $\xi \in L^p(F_1)$, for $p \geq 2$, let $(Y, Z)$ denote the solution to (1.3).

Then there exists a random variable $\xi \in L^p \setminus L^\infty$ for any $p \geq 2$ such that

$$\lim_{N \to \infty} E[|Y^{(N)}_{1/2}|] = +\infty,$$

where $Y^{(N)}_{1/2}$ is the Euler approximation of $Y$ on the time point $t = 1/2$ via (1.4) over the grids $\pi^N$.

The special random variable $\xi$ we work with is normally distributed and it is known that $P[|\xi| > 2\sqrt{N}]$ is exponentially small (see Lemma A.1). What our counter-example shows is that although $\xi$ may take very large values on an event with exponentially small probability, the impact of these very large values when propagated through the Euler explicit scheme is doubly-exponential (see (1.5)).

This double-exponential impact is precisely a consequence of the superlinearity of the driver. In general, the terminal condition $\xi$ is an unbounded random variable (RV) so there is a positive probability of the scenario where $\xi \geq 2\sqrt{N}$ no matter how small a time-step we choose. This indicates that, in general, the explicit Euler scheme may diverge, as it happens in SDE context [HJK11]. Therefore one needs to seek alternative (for example implicit) approximations for BSDE with polynomial drivers that are also monotone and/or find conditions under which it is possible for the explicit scheme to work, as explicit schemes have certain computational advantages over implicit ones.

**Our contribution**

- We extend the canonical Zhang path regularity theorem (see [MZ02], [IDR10b]), originally proved under Lipschitz assumptions, to our polynomial growth monotone driver setting proving in between all the required stochastic smoothness results; essentially all 1st order variations of the solution processes and estimates on the modulus of continuity.

- For our non-Lipschitz setting we provide a thorough analysis of the family of $\theta$-schemes, where $\theta \in [0,1]$ characterizes the degree of implicitness of the scheme. Contrary to the FBSDEs with Lipschitz driver we show that choosing $\theta \geq 1/2$ is essential to ensure the stability of the scheme, in a similar way to the SDE context (see [MS13]). This is to our knowledge the first result in the numerical BSDEs literature that shows a superior stability of the implicit scheme over the standard explicit one. We also generalize the concept of stability for discretization
schemes (see that in [Cha12] or [Cha13]). This, among others things, paves a way for deriving higher order approximations schemes for FBSDEs with non-Lipschitz drivers. As an example, we prove a higher order of convergence for the trapezoidal scheme (the case $\theta = 1/2$).

- We construct an appropriately tamed version of the explicit Euler scheme for which the required stability property can be recovered. This allows to obtain convergence of the scheme. Interestingly enough, in the special case where the driver of the FBSDEs does not depend on the SDE solution it is enough to appropriately tame the terminal condition, leaving the rest of the Euler approximation unchanged.

As a rule of thumb, implicit schemes tend to be more robust than explicit ones. Unfortunately implicit schemes involve solving an implicit equation, which creates an extra layer of complexity when compared to explicit schemes. A secondary aim of this work is to distinguish under which conditions explicit and implicit schemes can be used.

As standard in numerical analysis, we derive the global error estimates of various numerical schemes by analyzing their one-step errors and stability properties (which allows to study how errors propagate with time). We formulate the Fundamental Lemma (following the nomenclature from [MT04]) that states how to estimate the global error of a stable approximation scheme in terms of its local errors. The lemma is proved under minimal assumptions. We stress that a similar approach has been used in [CC12], [Cha12] and [Cha13], however their results are not sufficiently general to deal with non-Lipschitz drivers.

The structure of the global error estimate given by the Fundamental Lemma allows to study in a very easy and transparent way the special case of the $\theta$-scheme with $\theta = 1/2$ (trapezoidal rule) which has a higher order of convergence. In this context we also conjecture a candidate for the 2nd order scheme.

Concerning the implementation of the presented schemes we propose an alternative estimator of the component $Z$ whose standard deviation, contrary to usual estimator, does not explode as the time step vanishes.

Finally, we note that in proving convergence for the mostly-implicit schemes, we prove $L^p$-type uniform bounds for the scheme, thus extending the classical $L^2$-bound obtained previously for the discretization of Lipschitz FBSDEs (see [BT04], [GT14] and references therein etc).

This work is organized as follows. In Section 2 we define notation and recall standard results from the literature. In Section 3 we establish first order variational results for the solution of the FBSDEs as well as stating the path regularity results required for the study of numerical schemes within the FBSDE framework. The remaining sections contain the discussion of several numerical schemes: in Section 4 we define the numerical discretization procedure and state general estimates for integrability and on the local errors. In Section 5 we establish the convergence of the implicit dominating schemes and in Section 6 the convergence of the tamed explicit scheme (after the terminology of [HJK12]). In Section 7 we give some numerical examples.

2 Preliminaries

2.1 Notation

Throughout let us fix $T > 0$. We work on a canonical Wiener space $(\Omega, \mathcal{F}, \mathbb{P})$ carrying a $d$-dimensional Wiener process $W = (W^1, \cdots, W^d)$ restricted to the time interval $[0, T]$. We denote by $\mathcal{F} = (\mathcal{F}_t)_{t \in [0, T]}$ its natural filtration enlarged in the usual way by the $\mathbb{P}$-zero sets and by $\mathbb{E}$ and $\mathbb{E}[\cdot | \mathcal{F}_t] = \mathbb{E}_t[\cdot]$ the usual expectation and conditional expectation operator respectively.

For vectors $x = (x^1, \cdots, x^d)$ in the Euclidean space $\mathbb{R}^d$ we denote by $\| \cdot \|$ and $\langle \cdot, \cdot \rangle$ the canonical Euclidean norm and inner product (respectively) while $\| \cdot \|$ is the matrix norm in $\mathbb{R}^{k \times d}$ (when no ambiguity arises we use $\| \cdot \|$ as $\| \cdot \|$); for $A \in \mathbb{R}^{k \times d}$ $A^*$ denotes the transpose of $A$; $I_d$ denotes the $d$-dimensional identity matrix. For a map $b : \mathbb{R}^m \to \mathbb{R}^d$, we denote by $\nabla b$ its $\mathbb{R}^{d \times m}$-valued Jacobi matrix (gradient in case $d = 1$) whenever it exists. To denote the $j$-th first derivative of $b(x)$ for $x \in \mathbb{R}^m$ we write $\nabla_x b$ (valued in $\mathbb{R}^{d \times 1}$). For $b(x, y) : \mathbb{R}^m \times \mathbb{R}^d \to \mathbb{R}^k$ we write $\nabla_y b$ or $\nabla_y h$ to refer to its Jacobi matrix (gradient if $k = 1$) with relation to $x$ and $y$ respectively. $\Delta$ denotes the canonical Laplace operator.

We define the following spaces for $p > 1$, $q \geq 1$, $n, m, d, k \in \mathbb{N}$: $C_{0,n}^0([0, T] \times \mathbb{R}^d, \mathbb{R}^k)$ is the space of continuous functions endowed with the $\| \cdot \|_{\infty}$-norm that are $n$-times continuously differentiable in the spatial variable; $C_{0,n}^0$ contains all bounded functions of $C_{0,n}^0$; the first superscript 0 is dropped for functions independent of time; $L^p(\mathcal{F}_t, \mathbb{R}^d)$, $t \in [0, T]$, is the space of $d$-dimensional $\mathcal{F}_t$-measurable RVs $X$ with norm $\| X \|_{L^p} = \mathbb{E}[| X |^p]^{1/p} < \infty$; $L^\infty$ refers to the subset of essentially bounded RVs; $S^p([0, T] \times \mathbb{R}^d)$ is the space of $d$-dimensional measurable $\mathcal{F}$-adapted processes $Y$ satisfying $\| Y \|_{S^p} = \mathbb{E}[\sup_{t \in [0, T]} | Y_t |^p]^{1/p} < \infty$; $S^\infty$ refers to the subset of $S^p(\mathbb{R}^d)$ of absolutely uniformly bounded processes; $H^p([0, T] \times \mathbb{R}^{n \times d})$ is the space of $d$-dimensional measurable $\mathcal{F}$-adapted processes $Z$ satisfying $\| Z \|_{H^p} = \mathbb{E}[\int_0^T | Z_t |^2 ds]^{p/2} < \infty$; $D^{k,p}(\mathbb{R}^d)$ and $L_{k,d}(\mathbb{R}^d)$ are the spaces of Malliavin differentiable RVs and processes, see Appendix A.2.

2.2 Setting

We want to study the forward-backward SDE system with dynamics (1.1)-(1.2), for $(t, x) \in [0, T] \times \mathbb{R}^d$ and $\Theta^{t,x} := (X^{t,x}, Y^{t,x}, Z^{t,x})$. Here we work, for $s \in [t, T]$, with the filtration $\mathcal{F}_s^* := \sigma(W_r - W_t : r \in [t, s])$, completed with the $\mathbb{P}$-Null measure sets of $\mathcal{F}$. Concerning the functions appearing in (1.1) and (1.2) we will work with the following assumptions.

(HX0) \( b : [0, T] \times \mathbb{R}^d \to \mathbb{R}^d, \sigma : [0, T] \times \mathbb{R}^d \to \mathbb{R}^{d \times d} \) are 1/2-Hölder continuous in their time variable, are Lipschitz continuous in their spatial variables, satisfy $\| b(\cdot, 0) \|_{\infty} + \| \sigma(\cdot, 0) \|_{\infty} < \infty$ and hence satisfy $| b(\cdot, x) + \sigma(\cdot, x) | \leq K(1 + | x |)$ for some $K > 0$.

(HY0) \( g : \mathbb{R}^d \to \mathbb{R}^k \) is a Lipschitz function of linear growth; \( f : [0, T] \times \mathbb{R}^d \times \mathbb{R}^k \times \mathbb{R}^{d \times d} \to \mathbb{R}^k \) is a continuous function such that for some $L, L_x, L_y, L_z > 0$ for all $t, t', x, y, y', z, z'$
\[
| f(t, x, y, z) | \leq L + L_x | x | + L_y | y |^m + L_z | z |, \quad m \geq 1,
\]
\[
\langle y' - y, f(t, x, y', z) - f(t, x, y, z) \rangle \leq L_y | y' - y |^2,
\]
\[
| f(t, x, y, z) - f(t', x', y', z') | \leq L_t | t - t' |^{1/2} + L_x | x - x' | + L_z | z - z' |.
\]

(HY0_{k<}) (HY0) holds and, given $L_y$, it holds for all $t, x, y, y', z$ that
\[
| f(t, x, y, z) - f(t, x, y', z') | \leq L_y (1 + | y |^m - 1 + | y' |^m - 1) | y - y' |, \quad m \geq 1.
\]
We state in the next remark some useful consequences of the monotonicity condition (2.1).

**Remark 2.1.** Under Assumption (HY0), for all \( t, x, y, y', z, z' \) and any \( \alpha > 0 \) we have

\[
\langle y' - y, f(t, x, y', z') - f(t, x, y, z) \rangle = \langle y' - y, f(t, x, y', z') \rangle + \langle y' - y, f(t, x, y, z') - f(t, x, y, z) \rangle \\
\leq L_y |y' - y|^2 + L_x |y' - y||z' - z| \leq (L_y + \alpha)|y' - y|^2 + \frac{L_z^2}{4\alpha}|z' - z|^2.
\]

Moreover

\[
\langle y, f(t, x, y, z) \rangle = \langle y - 0, f(t, x, y, z) - f(t, x, 0, z) \rangle + \langle y, f(t, x, 0, z) \rangle \\
\leq L_y |y|^2 + |y|(|L + L_x|x| + L_z|z|) \leq (L_y + \alpha)|y|^2 + \frac{3L_x^2}{4\alpha} |x|^2 + \frac{3L_z^2}{4\alpha} |z|^2.
\]

### 2.3 Basic results

In this subsection we recall several auxiliary results concerning the solution of (1.1)-(1.2) that will become useful later. These results follow from [Par99] and [BC00].

**Theorem 2.2** (Existence and uniqueness). Let (HX0) and (HY0) hold. Then FBSDE (1.1)-(1.2) has a unique solution \((X, Y, Z) \in S^p \times S^p \times H^p\) for any \( p \geq 2 \). Moreover, it holds for some constant \( C_p > 0 \) that

\[
\|Y\|_{S^p}^p + \|Z\|_{H^p}^p \leq C_p \{ \|g(X_T)\|_{L^p}^p + \|f(\cdot, X_0, 0, 0)\|_{H^p}^p \} \leq C_p (1 + \|x\|^p). \tag{2.4}
\]

**Proof.** The existence and uniqueness results for SDE (1.1) follow from standard SDE literature. The existence and uniqueness result for the BSDE follows from Proposition 2.2 in [Par99], since the SDE results imply that \( X \in S^p \) for any \( p \geq 2 \), along with linear growth in \( x \) of \( g \) and \( f \). The estimates for \( Y \in S^p \) for any \( p \geq 2 \) and \( Z \in H^p \) follow from the pathwise inequality

\[
|Y_t|^2 + \left(1 - \frac{3L_z^2}{2\alpha}\right)\mathbb{E}_t \left[ \int_t^T |Z_u|^2 \, du \right] \leq C_{\alpha,T,z} \mathbb{E}_t \left[ |g(X_T)|^2 + \int_t^T \frac{3}{4\alpha} |f(u, X_u, 0, 0)|^2 \, du \right], \tag{2.5}
\]

where \( C_{\alpha,T,z} = \exp\left(2(L_y + \alpha)(T - t)\right) \), for any \( \alpha > 0 \) and \( t \in [0, T] \). This last inequality follows from the proof of Proposition 2.2 and Exercise 2.3 in [Par99], (see also Theorem 3.6 in [BC00]).

We now state a result concerning a priori estimates for BSDEs.

**Theorem 2.3** (A priori estimate). Let \( p \geq 2 \) and for \( i \in \{1, 2\} \), let \( \Theta^i = (X^i, Y^i, Z^i) \) be the solution of FBSDE (1.1)-(1.2) with functions \( b^i, \sigma^i, g^i, f^i \) satisfying (HX0)-(HY0). Then there exists \( C_p > 0 \) depending only on \( p \) and the constants in the assumptions such that for \( i \in \{1, 2\} \)

\[
\|Y^1 - Y^2\|_{S^p}^p + \|Z^1 - Z^2\|_{H^p}^p \leq C_p \left\{ \mathbb{E} \left[ |g^1(X^1_T) - g^2(X^2_T)|^p \right] + \left( \int_0^T |f^1(s, X^1_s, Y^1_s, Z^1_s) - f^2(s, X^2_s, Y^s_s, Z^2_s)| \, ds \right)^p \right\}. \tag{2.6}
\]

**Proof.** See Proposition 3.2 and Corollary 3.3 in [BC00].
Corollary 2.4 (Markov property and sample path continuity). Let (HX0) and (HY0) hold. The mapping \((t, x) \mapsto Y_t^{t,x}(\omega)\) is continuous. There exist two \(\mathcal{B}([0, T]) \otimes \mathcal{B}(\mathbb{R}^k)\) and \(\mathcal{B}([0, T]) \otimes \mathcal{B}(\mathbb{R}^{k \times d})\) measurable deterministic functions \(u\) and \(v\) (respectively) s.t.

\[
\begin{align*}
Y_t^{t,x} &= u(s, X_s^{t,x}) \quad s \in [t, T], \; d\mathbb{P} - a.s. \\
Z_s^{t,x} &= v(s, X_s^{t,x}) \sigma(s, X_s^{t,x}) \quad s \in [t, T], \; d\mathbb{P} \times ds - a.s.
\end{align*}
\]

Moreover, the Markov property holds \(Y_{t+h}^{t,x} = Y_{t}^{t+h, X_{t+h}^{t,x}}\) for any \(h \geq 0\) and \(u \in C^{0,0}([0, T] \times \mathbb{R}^k)\).

Proof. See Section 3 in [Par99]. The sample path continuity of \(Y_t^{t,x}\) follows from the mean-square continuity of \((Y_s^{t,x})_{s \in [t, T]}\) for \(x \in \mathbb{R}^k\), \(0 \leq t \leq s \leq T\), which in turn follows from inequality (2.6). Combined with the Lipschitz property of \(x \mapsto g(x)\) and \((t, x) \mapsto f(t, x, \cdot, \cdot)\) along with the continuity properties of \((t, x) \mapsto X_t^{t,x}\) solution to (1.1).

The Markov property follows from Remark 3.1 [Par99] and the continuity of \(u(t, x)\) is implied by that of \(Y_t^{t,x}\).

\[
\square
\]

2.4 Non-linear Feynman-Kac formula

As pointed out in the introduction, our aim is to deepen the connection between FBSDEs and PDEs via the so-called non-linear Feynman-Kac formula, i.e. we study the probabilistic representation of the solution to a class of parabolic PDEs on \(\mathbb{R}^k\) with polynomial growth coefficients that are associated with FBSDE (1.1)-(1.2). For \((t, x) \in [0, T] \times \mathbb{R}^d\), denote by \(L\) the infinitesimal generator of the Markov process \(X^{t,x}\) solution to (1.1)

\[
L := \frac{1}{2} \sum_{i,j=1}^d (|\sigma^*|_{ij})(t, x) \partial^2_{x_i x_j} + \sum_{i=1}^d b_i(t, x) \partial_{x_i},
\]

and consider for a function \(v = (v_1, \cdots, v_k)\) the following system of backward semi-linear parabolic PDEs for \(i \in \{1, \cdots, k\}\)

\[
-\partial_t v_i(t, x) - L v_i(t, x) - f_i(t, x, v(t, x), (\nabla v \sigma)(t, x)) = 0, \quad v(T, x) = g(x).
\]

In rough it can be easily proved using Itô’s formula that if \(v \in C^{1,2}([0, T] \times \mathbb{R}^d; \mathbb{R}^k)\) solves the above PDE then \(Y_t := v(t, X_t)\) and \(Z_t := (\nabla v \sigma)(t, X_t)\) solves BSDE (1.2) (see Proposition 3.1 in [Par99]). But the more interesting result is the converse one, i.e. that \(u(t, x) := Y_t^{t,x}\) is the solution of the PDE (in some sense). It was established in Theorem 3.2 of [Par99] (recalled next) that indeed \((t, x) \mapsto Y_t^{t,x}\) is the viscosity solution of the PDE.

Theorem 2.5. Let (HX0), (HY0) hold and take \((t, x) \in [0, T] \times \mathbb{R}^d\). Furthermore, assume that the \(i\)-th component of the driver function \(f\) depends only on the \(i\)-th row of the matrix \(z \in \mathbb{R}^{k \times d}\), i.e. \(f_i(t, x, y, z) = f_i(t, x, y, z)\).

Then \(u(t, x) := Y_t^{t,x}\) is a continuous function of \((t, x)\) that grows at most polynomially at infinity and is a viscosity solution of (2.9) (in the sense of Definition 3.2 in [Par99]).

Remark 2.6 (Multi-dimensional case). The proof of Theorem 2.5 relies on a BSDE comparison theorem that holds only in the case \(k = 1\) (i.e. when \(Y\) is one-dimensional). Nonetheless, with the restriction imposed by (HY0), it is still possible to use the said comparison theorem to prove Theorem 2.5, we point the reader to Theorem 2.4 and Remark 2.5 in [Par99].

It is possible to show that \((t, x) \mapsto Y_t^{t,x}\) is the solution to (2.9) not only in the viscosity sense, but also in weak sense (in weighted Sobolev spaces), this has been done in [MX08] and [ZZ12].
2.5 Examples

One equation covered by our setting is the FitzHugh-Nagumo PDE with recovery, used in biology and related to the modeling of the electrical distribution of the heart or the potential in neurons.

Example 2.7 (The FH-N equation with recovery). Let \((t,x) \in [0,T] \times \mathbb{R}^d\), \(g = (g_u,g_v)\), \(f = (f_u,f_v)\) and \(g,f,(u,v) : [0,T] \times \mathbb{R}^d \to \mathbb{R}^2\). The FH-N PDE has a dynamics of the type

\[-\partial_t u - \frac{1}{2} \Delta u - f_u(u,v) = 0, \quad -\partial_t v - \Delta v - f_v(u,v) = 0, \quad \text{with } u(T,\cdot) = g_u(\cdot), \quad v(T,\cdot) = g_v(\cdot),\]

where \(f_u(u,v) = u - u^3 + v\) and \(f_v(u,v) = u - v\). \(f\) clearly satisfies (HY0) and (HY0_{loc}).

A simpler setup of the above model is its 1-dimensional version.

Example 2.8 (FH-N equation without recovery). For \((t,x) \in [0,T] \times \mathbb{R}\) the FH-N equation without recovery is described by

\[-\partial_t u - \frac{1}{2} \Delta u - (cu^3 + bu^2 - au) = 0, \quad u(T,x) = g(x).\] (2.10)

When \(c = -1\), \(b = 1 + a\), \(a \in \mathbb{R}\) and with the particular choice of \(g(x) = (1 + e^x)^{-1}\), one can verify that the \(C^\infty_b\) solution \(u\) to (2.10) is given by

\[u(t,x) = \left(1 + \exp \{ x - (1/2 - a)(T - t) \} \right)^{-1} \in C^\infty_b([0,T] \times \mathbb{R}).\] (2.11)

The FBSDE corresponding to this PDE is given by (1.1)-(1.2) with the following data:

\[b(t,x) = 0, \quad \sigma(t,x) = 1, \quad \text{and } f(t,x,y,z) = cy^3 + by^2 - ay, \quad c = -1, \quad b = 1 + a,\]

and the terminal condition function \(g\) is given above. Both (HX0) and (HY0_{loc}) hold (for any \(a\), notice that \(u \geq 0\) for any \(a\)) and the theory we develop throughout applies to this class of examples. We will use the case \(a = -1\) in our simulations.

3 Representation results, path regularity and other properties

As seen before \(u(t,x) := Y^t_{t,x}\) is a viscosity solution of PDE (2.9). If \(u \in C^{1,2}\) we would also obtain the representation of the process \(Z\) as \(Z^{t_{i+1}}_{t_i} = (\nabla_x u \sigma)(t,x)\), but in view of Theorem 2.5 we have not given meaning to \(\nabla_x u\). The main aim of this section is to first prove some representation formulas, that express \(Z\) as a function of \(Y\) and \(X\), then use these representation formulas to obtain the so called \(L^2\) (and \(L^p\)) path regularity results needed to prove the convergence of the numerical discretization of FBSDE (1.1)-(1.2) in the later sections. A by-product of these results is the existence of \(\nabla_x u\).

3.1 Differentiability in the spatial parameter

Take the system (1.1)-(1.2) into account. We now show that the smoothness of the FBSDE parameters \(b,\sigma,g,f\) carries over to the solution process \(\Theta = (X,Y,Z)\).
Theorem 3.1. Let (HXY1) hold and \((t, x) \in [0, T] \times \mathbb{R}^d\).

Then \(u\) (from (2.7)) is continuously differentiable in its spatial variable. Moreover, the triple \(\nabla_x \Theta^{l,x} = (\nabla_x X^{l,x}, \nabla_x Y^{l,x}, \nabla_x Z^{l,x}) \in S^p \times S^p \times H^p\) for any \(p \geq 2\) and solves for \(0 \leq t \leq s \leq T\)

\[
\begin{align*}
\nabla_x X_i^{l,x} &= I_d + \int_t^s (\nabla_x b)(r, X_i^{l,x}) \nabla_x X_i^{l,x} \, dr + \int_t^s (\nabla_x \sigma)(r, X_i^{l,x}) \nabla_x X_i^{l,x} \, dW_r, \\
\nabla_x Y_i^{l,x} &= (\nabla_x g)(X_i^{l,x}) \nabla_x X_i^{l,x} - \int_t^s \nabla_x Z_i^{l,x} \, dW_r + \int_t^s F(r, \nabla_x \Theta^{l,x}) \, dr
\end{align*}
\] (3.1)

for \(i \in \{1, \ldots, d\}\) and with\(^2\)

\[
F : (\omega, r, x, \chi, Y, \Gamma) \mapsto (\nabla_x f)(r, \Theta_r^{l,x}) \cdot \chi + (\nabla_y f)(r, \Theta_r^{l,x}) \cdot Y + (\nabla_z f)(r, \Theta_r^{l,x}) \cdot \Gamma.
\]

There exists a positive constant \(C_p\) independent of \(x\) such that

\[
\sup_{(t,x) \in [0, T] \times \mathbb{R}^d} \| (\nabla_x Y^{l,x}, \nabla_x Z^{l,x}) \|_{S^p \times H^p} \leq C_p.
\] (3.2)

Furthermore, for \(u\) as in (2.7) we have for \(x \in \mathbb{R}^d\) and \(0 \leq t \leq s \leq T\)

\[
\nabla_x Y_i^{l,x} = (\nabla_x u)(s, X_i^{l,x}) \nabla_x X_i^{l,x} \quad \text{P-a.s. and } \| \nabla_x u \|_{\infty} < \infty.
\] (3.3)

We recall that \(\nabla_x Y^{l,x}\) is \(\mathbb{R}^k\)-valued and \(\nabla_x Y_i^{l,x}\) denotes its \(i\)-th column. Similar notation follows for \(\nabla_x X\) and \(\nabla_x Z\).

Proof. Throughout fix \((t, x) \in [0, T] \times \mathbb{R}^d\) and let \(\{e_i\}_{i \in \{1, \ldots, d\}}\) be the canonical unit vectors of \(\mathbb{R}^d\). Let \(i \in \{1, \ldots, d\}\).

The results concerning SDE (1.1) follow from those in Subsection 2.5 in [IDR10]. We start by showing that the partial derivatives \((\nabla_x Y^{l,x}, \nabla_x Z^{l,x})\) for any \(i\) exist, then we will show the full differentiability. We start by proving that (3.1) has indeed a solution for every \(i\). Unfortunately, the driver of (3.1) does not satisfy (HY0) and hence we cannot quote Theorem 2.2 directly; we use a more general result from [BDHS03]. We remark though, that the techniques used to obtain moment estimates of the form of (2.4) and (2.6) are the same in both [BDHS03] and [Par99].

FBSDE (3.1) has a unique solution \(\Xi_i^{l,x} := (\nabla_x X_i^{l,x}, U_i^{l,x}, Y_i^{l,x}, Y_i^{l,x}) \in S^p \times S^p \times H^p\) for any \(p \geq 2\), where \((U^i, V^i)\) replaces \((\nabla_x Y, \nabla_x Z)\). This follows by a direct application of Theorem 4.2 in [BDHS03]. It is easy to see that under (HXY1) the conditions (H1)-(H5) in [BDHS03] (p118-119) are satisfied. First, under (HXY1), standard SDE theory (see e.g. Theorem 2.4 in [IDR10]) ensures that \(\nabla_x X \in S^p\) for all \(p \geq 2\), which along with \(\nabla_x g, \nabla_x f \in C^0_b\) implies in turn that the terminal condition \((\nabla_x g)(X_T^{l,x}) \nabla_x X_i^{l,x} \in L^p_{T,T}\) and the term \((\nabla_x f)(\cdot, \Theta_r^{l,x}) \nabla_x X_i^{l,x} = F(\cdot, \nabla_x X_i^{l,x}, 0, 0) \in S^p\) for any \(p \geq 2\). Given the linearity of \(F\) and the Lipschitz property of \(f\) in its \(z\)-variable it follows that \(F\) is uniformly Lipschitz in \(\Gamma\). Moreover, since \(f\) satisfies (2.1) it implies that \(F\) is monotone\(^3\) in \(\Gamma\), i.e.

\[
\langle \Upsilon - \Upsilon', (\nabla_y f)(r, \Theta_r^{l,x}) \cdot (\Upsilon - \Upsilon') \rangle \leq L_y |\Upsilon - \Upsilon'|^2, \quad \text{for any } \Upsilon, \Upsilon' \in \mathbb{R}^k.
\] (3.4)

The continuity of \(\Upsilon \mapsto F(r, x, \chi, \Upsilon, \Gamma)\) is also clear. Lastly, the linearity of \(F\), the fact that \(\Theta \in S^p \times S^p \times H^p\) for any \(p \geq 2\) and (2.2) implies that condition (H5) in [BDHS03] is also satisfied, i.e. that for any \(R > 0\), \(\sup_{|\Upsilon| \leq R} |F(r, x, \nabla_x X_i^{l,x}, \Upsilon, 0) - F(r, x, \nabla_x X_i^{l,x}, 0, 0)| \in L^1([t, T] \times \Omega)\). We are therefore under the conditions of Theorem 4.2 in [BDHS03], as claimed.

\(^2\)The term \((\nabla_x f)(\cdot, \Theta_r \cdot \Gamma)\) can be better understood if one interprets \(z\) in \(f\) not as in \(\mathbb{R}^{k \times d}\) but as \((\mathbb{R}^d)^k\), i.e. \(f\) receives not a matrix but its \(\mathbb{R}^d\)-valued \(k\) lines.

\(^3\)This follows easily from the differentiability of \(f\), its monotonicity in \(y\) and the definition of directional derivative.
In view of (2.3) and the linearity of $F$ one can obtain moment estimates in the style of (2.4) by following arguments similar to those in the proof of Theorem 2.2 (recall that (2.3) takes in this case a very simple form). In view of (2.4), we have (recall that $\nabla X \in \mathcal{S}^p$ for all $p \geq 2$)

$$
\|U^i\|_{\mathcal{S}^p}^p + \|V^i\|_{\mathcal{H}^p}^p \leq C_p \left\{ \|g(X^i_T)\nabla X^i_T, X^i_T\|_{\mathcal{S}^p}^p + \|g(X_T)\nabla X_T, X^i_T\|_{\mathcal{H}^p}^p \right\} \\
\leq C_p \|\nabla X, X^i_T\|_{\mathcal{S}^p}^p \leq C_p,
$$

(3.5)

where $C_p$ does not depend on $x, t$ or $i$.

In order to obtain results on the first order variation of the solution, we follow standard BSDE techniques used already in [IDR10b], [BC08] or [DRRZ11]; we start by studying the behavior of $\Theta^{t,x,\varepsilon,i} - \Theta^{t,x}$ for any $\varepsilon > 0$. Take $h \in \mathbb{R}^d$. Via the stability of SDEs and inequality (2.6) (and (HY0)), it is clear that a constant $C_p > 0$ independent of $x$ exists such that

$$
\lim_{h \to 0} \|\Theta^{t,x+h} - \Theta^{t,x}\|_{\mathcal{S}^p \times \mathcal{S}^p \times \mathcal{H}^p} \leq \lim_{h \to 0} C_p \|X^{t,x+h} - X^{t,x}\|_{\mathcal{S}^p} \leq \lim_{h \to 0} C_p |h| = 0.
$$

(3.6)

Define $\delta \Theta^{t,i} := (\delta X^{t,i}, \delta Y^{t,i}, \delta Z^{t,i}) := (\Theta^{t,x,\varepsilon,i} - \Theta^{t,x}) / \varepsilon - (\nabla_{x,i} X^{t,x}, U^{t,x,i}, V^{t,x,i})$ for which

$$
\delta Y^{t,s,i}_s = \left[ \frac{1}{\varepsilon} (g(X^{t,x,\varepsilon,i}_s) - g(X^{t,x}_s)) - \nabla_x g(X^{t,x}_s) \nabla X^{t,x}_s \right] - \int_s^T \delta Z^{t,i}_r dW_r \\
+ \int_s^T \left[ \frac{1}{\varepsilon} (f(r, \Theta^{t,x,\varepsilon,i}_s) - f(r, \Theta^{t,x}_s)) - F(r, x, \nabla X^{t,x}_s, U^{t,x,i}_s, V^{t,x,i}_s) \right] dr.
$$

(3.7)

Using the differentiability of the involved functions we can re-write (3.7) as a linear FBSDE with random coefficients satisfying in its essence a (HY0) type assumption: for $s \in [t, T], j \in \{1, \cdots, d\}$

$$
\begin{align*}
\delta X^{t,s,j}_s &= 0 + f^s_t \left[ b^{t,j}_r(r) \delta X^{t,j}_r + \delta \nabla b^{t,j}_r \nabla X^{t,j}_r \right] dr + \int_s^T \left[ \sigma^{t,j}_r(r) \delta X^{t,j}_r + \delta \nabla \sigma^{t}_r \nabla X^{t,\varepsilon,i}_r \right] dW_r, \\
\delta Y^{t,s,i}_s &= \left[ g^{t,i}_s(T) \delta X^{t,i}_s + \delta \nabla g^{t,i}_s \nabla X^{t,i}_s \right] - \int_s^T \delta Z^{t,i}_r dW_r \\
&+ \int_s^T \left[ f^{t,i}_s(r) \delta X^{t,i}_s + f^{t,i}_r(r) \delta Y^{t,i}_s + f^{t,i}_s(r) \delta Z^{t,i}_s + \delta \nabla \varphi^t \cdot (\nabla_{x,i} X^{t,i}_s, U^{t,x,i}_s, V^{t,x,i}_s) \right] dr,
\end{align*}
$$

(3.8)

where $\delta \nabla f$ and $\delta \nabla \varphi$ denote the differences

$$
\delta \nabla f^t := (f^t_i, f^t_j, f^t_z)(\cdot) - (\nabla_X f, \nabla_y f, \nabla_z f)(\cdot, \Theta^{t,i}_x),
$$

and

$$
\delta \nabla \varphi^t := \varphi^{t,i}_x(\cdot) - \nabla_x \varphi(\cdot, \Theta^{t,i}_x),
$$

for $\varphi \in \{b, \sigma, g\}$ (with some abuse of notation) and $r \in [t, T]$, and where we defined

$$
\varphi^{t,i}_x(r) := \int_r^t (\nabla_x \varphi)(r_1, (1 - \lambda)X^{t,x}_r + \lambda X^{t,x+\varepsilon,i}_r) d\lambda = \int_r^t (\nabla_x \varphi)(r, X^{t,x}_r + \lambda (X^{t,x+\varepsilon,i}_r - X^{t,x}_r)) d\lambda,
$$

and $f^{t,i}_s$ for $s \in \{x, y, z\}$ in the following way:

$$
\begin{align*}
f^{t,i}_x(r) &= \int_r^t (\nabla_x f)(r, X^{t,x+\varepsilon,i}_r, Y^{t,x+\varepsilon,i}_r, Z^{t,x}_r + \lambda (Z^{t,x+\varepsilon,i}_r - Z^{t,x}_r)) d\lambda, \\
f^{t,i}_y(r) &= \int_r^t (\nabla_y f)(r, X^{t,x+\varepsilon,i}_r, Y^{t,x+\varepsilon,i}_r + \lambda (Y^{t,x+\varepsilon,i}_r - Y^{t,x}_r), Z^{t,x}_r) d\lambda, \\
f^{t,i}_z(r) &= \int_r^t (\nabla_Z f)(r, X^{t,x+\varepsilon,i}_r + \lambda (X^{t,x+\varepsilon,i}_r - X^{t,x}_r), Y^{t,x+\varepsilon,i}_r, Z^{t,x}_r) d\lambda.
\end{align*}
$$

10
We remark that in the above limit a localization argument for the convergence of $f_y^{\varepsilon, i}(\cdot)$ is required, namely that we work inside a ball (of any given radius) centered around $x$.

Since the limit exists we identify with the dominated convergence theorem, one has

$$
\phi(3.5), (3.6), \text{ the continuity of } \phi \in \{b, \sigma, g\} \text{ and its derivative it is easy to see that, in combination}
$$

with the dominated convergence theorem, one has

$$
\lim_{\varepsilon \to 0} \left\{ \| \phi^{\varepsilon, i}(\cdot) - \nabla_x \phi(\cdot, \Theta^{i,x}) \|_{S^p} + \| \left( f^{\varepsilon, i}, f_y^{\varepsilon, i}, f_z^{\varepsilon, i} \right)(\cdot) - \left( \nabla_x f, \nabla_y f, \nabla_z f \right)(\cdot, \Theta^{i,x}) \|_{H^p} \right\} = 0. \quad (3.9)
$$

We remark that in the above limit a localization argument for the convergence of $f_y^{\varepsilon, i}(\cdot)$ to $\nabla_y f(\cdot, \Theta)$ is required, namely that we work inside a ball (of any given radius) centered around $x$ in which all points $x + \varepsilon e_i \in \mathbb{R}^d$ as $\varepsilon$ vanishes are contained. We do not detail the argumentation since it is similar to that given in e.g. [IDR10b], [BC08] or [DPRZ11].

With this in mind we return to (3.7), written in the form of (3.8), and since it is a linear FBSDE satisfying the monotonicity condition (2.1) we have by Corollary 3.3 in [BC00] (essentially our moment estimate (2.4) for FBSDE (3.8)) in combination with (3.5), (3.6) and (3.9), that for any $i$

$$
\lim_{\varepsilon \to 0} \| \left( \Theta^{i,x+e_\varepsilon} - \Theta^{i,x} \right) - \left( \nabla_x X^{t,x}, U^{t,x}, V^{t,x} \right) \|_{S^p \times S^p \times H^p} = 0, \quad \text{for any } p \geq 2.
$$

Since the limit exists we identify $\left( \nabla_x X^{t,x}, \nabla_x Z^{t,x} \right)$ with $(U^{t,x}, V^{t,x})$ and, moreover, estimate (3.5) implies estimate (3.2). Furthermore, the above limit implies in particular that (take $s = t$

$$
\nabla_x u(t, x) = \lim_{\varepsilon \to 0} \frac{1}{\varepsilon} [u(t, x + \varepsilon e_i) - u(t, x)] = \lim_{\varepsilon \to 0} \frac{1}{\varepsilon} [Y^{t,x+e_\varepsilon} - Y^{t,x}] = \nabla_x Y^{t,x}.
$$

Observing that the RHS of (3.5) is a constant independent of $t \in [0, T]$, $x \in \mathbb{R}^d$ and $i \in \{1, \cdots, d\}$ we can conclude that

$$
\| \nabla_x u \|_\infty = \sup_{(t,x)\in[0,T] \times \mathbb{R}^d} \| \nabla_x Y^{t,x} \|_\infty < \infty. \quad (3.10)
$$

It is clear that $\left( \nabla_x Y^{s,x}_s \right)_{s \in [0,T]}$ is continuous in its time parameter as it is a solution to a BSDE; we now focus on the continuity of $x \mapsto \nabla_x Y^{t,x}_t$. Let $x, x' \in \mathbb{R}^d$. The difference $\nabla_x Y^{t,x} - \nabla_x Y^{t,x'}$ is the solution to a linear FBSDE following from (3.1). As before, it is easy to adapt the computations and apply Corollary 3.3 in [BC00] (essentially our moment estimate (2.4) for FBSDEs (3.1)) to the difference $\nabla_x Y^{t,x}_s - \nabla_x Y^{t,x'}_s$ yielding

$$
\| \nabla_x Y^{t,x} - \nabla_x Y^{t,x'} \|_{S^2}^2 \\
\leq C_p \left\{ \| (\nabla_x g)(X^{t,x}_T, X^{t,x'}_T) \nabla_x X^{t,x} - (\nabla_x g)(X^{t,x}_T) \nabla_x X^{t,x'} \|_{L^2}^2 \right\} \\
+ \mathbb{E} \left[ \left( \int_0^T \left| F(r, x, \nabla_x X^{t,x}_r, \nabla_x Y^{t,x}_r, \nabla_x Z^{t,x}_r) - F(r, x', \nabla_x X^{t,x'}_r, \nabla_x Y^{t,x'}_r, \nabla_x Z^{t,x}_r) \right| ds \right]^p \right\}.
$$

Given the known results on SDEs, the linearity of $F$, (3.5), the continuity of the derivatives of $f$ and $(3.6)$, dominated convergence theorem yields that $\| \nabla_x Y^{t,x} - \nabla_x Y^{t,x'} \|_{S^2} \to 0$ as $x' \to x$ uniformly on compact sets. This mean-square continuity of $\nabla_x Y^{t,x}$ implies in particular that $\nabla_x Y^{t,x}_t = \nabla_x u(t, x)$ is continuous. In conclusion, we just proved that for any $i \in \{1, \cdots, d\}$ the partial derivatives $\nabla_x u$ exist and are continuous, hence, standard multi-dimensional real analysis implies that $u$ is continuously differentiable in its spatial variables. This argumentation is similar to that in the proof of Corollary 2.4.

We are left to prove (3.3). Note that for any $\varepsilon > 0$ we have $(Y^{t,x+e_\varepsilon}_s - Y^{t,x}_s) / \varepsilon = (u(s, X^{t,x+e_\varepsilon}_s) - u(s, X^{t,x}_s)) / \varepsilon$. By sending $\varepsilon \to 0$ and using the (continuous) differentiability of $u$, we have $\nabla_x Y^{t,x}_s = (\nabla_x u)(s, X^{t,x}_s) \nabla_x X^{t,x}_s$. Hence, as the RHS of (3.5) is a constant independent of $t \in [0, T]$, $x \in \mathbb{R}^d$ and $i$ we can conclude (let $s \searrow t$) that $\| \nabla_x u \|_\infty = \sup_{(t,x)\in[0,T] \times \mathbb{R}^d} \| \nabla_x Y^{t,x} \|_\infty < \infty$. □
3.2 Malliavin differentiability

As in the previous section we show a form of regularity of the solution $\Theta$ to (1.1)-(1.2), namely the stochastic variation of $\Theta$ in the sense of Malliavin's calculus.

**Theorem 3.2** (Malliavin differentiability). Let (HXY1) hold. Then the solution $\Theta = (X,Y,Z)$ of (1.1)-(1.2) verifies

- $X \in \mathbb{L}^{1,2}$ and $DX$ admits a version $(u,t) \mapsto D_u X_t$ satisfying for $0 \leq u \leq t \leq T$

  $$D_u X_t = \sigma(u,X_u) + \int_u^t (\nabla b)(s,X_s)D_u X_s ds + \int_u^t (\nabla \sigma)(s,X_s)D_u X_s dW_s.$$  

  Moreover, for any $p \geq 2$ there exists $C_p > 0$ such that

  $$\sup_{u \in [0,T]} \|D_u X\|_{\mathbb{S}^p} \leq C_p(1 + |x|^p). \quad (3.11)$$

- for any $0 \leq t \leq T$, $x \in \mathbb{R}^n$ we have $(Y,Z) \in \mathbb{L}^{1,2} \times (\mathbb{L}^{1,2})^d$. A version of $(DY,DZ)_{0 \leq u \leq t \leq T}$ satisfies: for $t < u \leq T$, $D_u Y_t = 0$ and $D_u Z_t = 0$, and for $0 \leq u \leq t$,

  $$D_u Y_t = (\nabla g)(X_T)D_u X_T + \int_t^T \langle (\nabla f)(s,\Theta_s), D_u \Theta_s \rangle ds - \int_t^T D_u Z_s dW_s. \quad (3.12)$$

  Moreover, $(D_1 Y_t)_{0 \leq t \leq T}$ defined by the above equation is a version of $(Z_t)_{0 \leq t \leq T}$.

- the following representation holds for any $0 \leq u \leq t \leq T$ and $x \in \mathbb{R}^n$

  $$D_u X_t = \nabla_x X_t (\nabla_x X_u)^{-1} \sigma(u,X_u) \mathbb{1}_{[0,u]}(t), \quad D_u Y_t = \nabla_x Y_t (\nabla_x X_u)^{-1} \sigma(u,X_u), \quad a.s., \quad (3.13)$$

  $$Z_t = \nabla_x Y_t (\nabla_x X_t)^{-1} \sigma(s,X_t), \quad a.s. \quad (3.14)$$

**Remark 3.3** (Y is already in $\mathbb{L}^{1,2}$). Via Theorem 3.1 we know that $u \in C^{0,1}$. Under (HXY1) it is known that $X \in \mathbb{L}^{1,2}$ (see [Nua06]) hence using the chain rule (for Malliavin calculus, see Proposition 1.2.3 in [Nua06]) we obtain $Y = u(\cdot, X) \in \mathbb{L}^{1,2}$. A careful analysis of Theorem 3.1 and the results about $\nabla_x u$ show that indeed $X,Y \in \mathbb{L}^{1,p}$ for all $p \geq 2$ (just combine (3.11) with (A.1) as described in Appendix Subsection A.2).

Using the fact that $X,Y \in \mathbb{L}^{1,2}$, the statement of Theorem 3.2 follows easily if the driver $f$ in (1.2) does not depend on $z$. One would argue in the following way: for any $t \in [0,T]$

$$\left( g(X_T) - Y_t + \int_t^T f(r,X_r,Y_r)dr \right)_{t \in [0,T]} \in \mathbb{L}^{1,2} \Rightarrow \left( \int_t^T Z_r dW_r \right)_{t \in [0,T]} \in \mathbb{L}^{1,2} \iff Z \in \mathbb{L}^{1,2},$$

this follows from the definition of the BSDE (1.2) itself and Theorem A.3. The dynamics of (3.12) and the representation formulas (3.14), (3.15) follow by arguments similar to those given below.

**Proof of Theorem 3.2.** The first part of the statement is trivial as it follows from standard SDE theory, see e.g. [Nua06] or Theorem 2.5 in [IDR10b]. To prove the other statements of the theorem, we will use an identification trick by taking advantage of the fact we already know that $Y \in \mathbb{L}^{1,2}$ (see Remark 3.3).
Let $(X,Y,Z)$ be the solution of (1.1)-(1.2) and define the following BSDE:

$$U_t = g(X_T) + \int_t^T \hat{f}(r,V_r)dr - \int_t^T V_r dW_r,$$

(3.16)

where the driver $\hat{f} : \Omega \times [0,T] \times \mathbb{R}^d \rightarrow \mathbb{R}$ is defined as

$$\hat{f}(t,v) := f(t,X_t,Y_t,v) = f(t,X_t,u(t,X_t),v).$$

(3.17)

It is clear that: $g(X_T) \in \mathbb{D}^{1,2}$, $f(\cdot,X,Y,0) \in \mathbb{L}^{1,p}$ for all $p \geq 2$ (see Remark 3.3) and that $v \mapsto \hat{f}(\cdot,v)$ is a Lipschitz continuous function, all these imply in particular via Lipschitz BSDE theory (see Theorem 2.1, Proposition 2.1 in [EKPQ97]) that there exists a pair $(U,V) \in \mathcal{S}^2 \times \mathcal{H}^2$ solving (3.16). Furthermore, Theorem 2.2 in [EKPQ97] states that the solution to (1.2) is unique and hence the solution of (3.16) verifies $(U,V) = (Y,Z)$.

Proposition 5.9 in [EKPQ97], yields the existence of the Malliavin derivatives $(DU,DV)$ of $(U,V)$ with the following dynamics. Set $\Xi := (X,Y,V)$, then for $t < u \leq T$ we have $D_uU_t = 0$, $D_uV_t = 0$ and

$$D_uU_t = (\nabla g)(X_T)D_uX_T + \int_t^T \langle (\nabla f)(s,\Xi_s), (D_u\Xi_s) \rangle ds - \int_t^T D_uV_s dW_s, \quad 0 \leq u \leq t.$$ 

Since $(U,V) = (Y,Z)$ then from the above BSDE for $(DU,DV)$ follows BSDE (3.12). Moreover, Proposition 5.9 in [EKPQ97] yields (3.14) and (3.15) for $(U,V)$ which carry out for $(Y,Z)$. \hfill $\Box$

3.3 Representation results

Here we combine the results of the two previous subsections to obtain representation formulas that will allow us to establish the path regularity properties of $Y$ and $Z$ required for the convergence proof of the numerical discretization.

**Theorem 3.4.** Let $(HXY1)$ hold, then the following representation holds

$$Z_s^{t,x} = (\nabla x u)(s,X_s^{t,x})0 \leq t \leq s \leq T \; \mathbb{dP} \text{-a.s.} \quad (3.18)$$

$$= \nabla x X_s^{t,x} (\nabla x X_s^{t,x})^{-1} \sigma(s,X_s^{t,x})0 \leq t \leq s \leq T \; \mathbb{dP} \text{-a.s.} \quad (3.19)$$

and $\|Z\|_{\mathcal{H}^q} \leq C_q(1 + |x|^q), \quad q \geq 2$.

Assume that only $(HX0)$ and $(HY0_{loc})$ hold, then for some $C > 0$ it holds $|Z_t| \leq C|\sigma(X_t)| dt \otimes \mathbb{dP}$-a.s. and in particular

$$|Z_t| \leq C(1 + |X_t|), \quad dt \otimes \mathbb{dP}$-a.s. \quad (3.20)$$

**Proof.** We first prove all the results under $(HXY1)$, then argue via mollification that (3.20) holds under $(HX0)$-$(HY0_{loc})$.

**Proof under $(HXY1)$:** The representation $Z = \nabla Y(\nabla X)^{-1}\sigma(\cdot,X)$ follows from Theorem 3.2, while from Theorem 3.1 we have

$$Z_s^{t,x} = \nabla x X_s^{t,x} (\nabla x X_s^{t,x})^{-1} \sigma(s,X_s^{t,x}) = (\nabla x u)(s,X_s^{t,x}) \left(\nabla x X_s^{t,x} (\nabla x X_s^{t,x})^{-1}\right) \sigma(s,X_s^{t,x})$$

$$= (\nabla x u)(s,X_s^{t,x}) \sigma(s,X_s^{t,x}).$$

Since all the involved processes (in the RHS) are continuous we can identify $Z$ with its continuous version. Moreover, as all the processes in the RHS belong to $\mathcal{S}^p \text{ for any } p \geq 2$ it follows that $Z \in \mathcal{S}^p$ for 13
all \( p \geq 2 \). Combining Hölder’s inequality with the fact that \( X, \nabla X \in \mathcal{S}^p \) for all \( p \geq 2 \) and estimate (3.2), leads to (3.20), i.e.

\[
\|Z\|_{\mathcal{S}^p} = \|\nabla_x Y_t^{l,x}(\nabla_x X_t^{l,x})^{-1}\sigma(\cdot, X_t^{l,x})\|_{\mathcal{S}^p} \\
\leq C_p\|\nabla_x Y_t^{l,x}\|_{\mathcal{S}^{2p}} \|\nabla_x X_t^{-1}\|_{\mathcal{S}^{2p}} |1 + X_t^{l,x}|_{\mathcal{S}^p} \leq C_p(1 + |x|).
\]

(3.21)

A careful inspection of the used inequalities shows that the constant \( C_p \) in (3.21) depends only on the several constants appearing in the assumptions (HX0)-(HY0) and (HY0) in (3.20).

**Proof of (3.20) under (HX0)-(HY0):** In this step we rely on a standard mollification arguments similar to those in the proof of Theorem 5.2 in [IDR10b]. Note that a driver satisfying (HY0) once mollified will still satisfy assumption (HY0) with the same constants.

Let \( b^n, \alpha^n, g^n, f^n \) as mollified versions of \( b, \alpha, g, f \) in their spatial variables such that the mollified functions satisfy uniformly (in \( n \)) (HX0) and (HY0), with uniform Lipschitz and monotonicity constants. Theorem 2.2 ensures that \( \Theta = (X^n, Y^n, Z^n) \in \mathcal{S}^p \times \mathcal{S}^p \times \mathcal{H}^p \) for any \( p \geq 2 \) and solves (1.1)-(1.2) with \( b^n, \sigma^n, g^n, f^n \) replacing \( b, \alpha, g, f \). Since the mollified functions satisfy (HY1) it follows from the above proof that for each fixed \( n \) we have \( Z^n \in \mathcal{S}^p \). Moreover, in view of (2.6) and the standard theory of SDEs it is rather simple to deduce that \( \Theta^n \to \Theta \) as \( n \to \infty \) in \( \mathcal{S}^p \times \mathcal{S}^p \times \mathcal{H}^p \) for all \( p \geq 2 \). Let \( u^n \) denote the solution to the PDE linked to FBSDE (1.1)-(1.2) with data \( b^n, \sigma^n, g^n, f^n \) and we drop the superscript \( (t,x) \) and work with \( (X^n, Y^n, Z^n) \).

From (3.18) we have \( |Z^n_s| = |(\nabla_x u^n(\sigma^n)(s, X^n_s)| \) at least \( ds \otimes dP \)-a.s. From (3.10) (or (3.2)) we can conclude that \( |\nabla_x Y_t^{l,x,n}| = |\nabla_x u^n(t, x)| \leq C \), with \( C \) independent of \( n \) and hence quite easily that

\[
|Z^n_s| \leq C|\sigma^n(s, X^n_s)| \leq C(1 + |X^n_s|) \quad ds \otimes dP \text{-a.s.}
\]

(3.22)

where we last used the linear growth condition of \( \sigma^n \).

Finally combine: the pointwise convergence of \( \sigma^n \to \sigma \) (knowing that all \( \sigma^n \) and \( \sigma \) have the same Lipschitz constant); the fact that \( X^n \to X \) in \( \mathcal{S}^p \) (standard SDE stability theory); and Theorem 2.3 yielding that \( Z^n \to Z \) in \( \mathcal{H}^p \) to conclude that (3.22) holds in the limit.

\[ \square \]

### 3.4 Path regularity results

Now let \( \pi \) be a partition of the interval \([0, T]\), say \( 0 = t_0 < \cdots < t_i < \cdots < T_N = T \), and mesh size \( |\pi| = \max_{i=0, \ldots, N-1} (t_{i+1} - t_i) \). Given \( \pi \), we also consider \( r_{\pi} = |\pi|/(\min_{i=0, \ldots, N-1} (t_{i+1} - t_i)) \).

Let \( Z \) be the control process in the solution to BSDE (1.2), under (HX0)-(HY0). We define a set of random variables \( \{\bar{Z}_{t_i}, t_i \in \pi\} \) term wise given by

\[
\bar{Z}_{t_i} = \frac{1}{t_{i+1} - t_i} \mathbb{E}\left[ \int_{t_i}^{t_{i+1}} Z_s \, ds \mid \mathcal{F}_{t_i} \right], \quad 0 \leq i \leq N - 1, \text{ and } \bar{Z}_{t_N} = Z_T.
\]

(3.23)

The RV \( Z_T \) can be obtained using (3.18), namely \( Z_T = (\nabla_x g)(X_T)\sigma(T, X_T) \) when \( g \in C^1 \). If \( g \) is only Lipschitz continuous then one easily sees that a RV \( G \in L^\infty(\mathcal{F}_T) \) exists such that \( Z_T = G\sigma(T, X_T) \). In any case, under (HX0) and (HY0) it easily follows that

\[
\bar{Z}_{t_i} = Z_T \in L^p(\mathcal{F}_T) \quad \text{for any } p \geq 2 \quad \text{and} \quad \bar{Z}_{t_i} \in L^2 \quad \text{for any } t_i \in \pi.
\]

(3.24)

It is not difficult to show that \( \bar{Z}_{t_i} \) is the best \( \mathcal{F}_{t_i} \)-measurable square integrable RV approximating \( Z \) in \( \mathcal{H}^2([t_i, t_{i+1}]) \), i.e.

\[
\mathbb{E}\left[ \int_{t_i}^{t_{i+1}} |Z_s - \bar{Z}_{t_i}|^2 \, ds \right] = \inf_{\xi \in L^2(\Omega, \mathcal{F}_{t_i})} \mathbb{E}\left[ \int_{t_i}^{t_{i+1}} |Z_s - \xi|^2 \, ds \right].
\]

(3.25)
Let now $\bar{Z}_t := \bar{Z}_{t_0}$ for $t \in [t_i, t_{i+1}), 0 \leq i \leq N - 1$. It is equally easy to see that $\bar{Z}$ converges to $Z$ in $H^2$ as $|\pi|$ vanishes: since $Z$ is adapted, the family of processes $Z^\pi$ indexed by our partition defined by $Z^\pi_t = Z_{t_i}$ for $t \in [t_i, t_{i+1})$ converges to $Z$ in $H^2$ as $|\pi|$ goes to zero. Since $\{\bar{Z}\}$ is the best $H^2$-approximation of $Z$, we obtain

$$\|Z - \bar{Z}\|_{H^2} \leq \|Z - Z^\pi\|_{H^2} \to 0, \quad \text{as } |\pi| \to 0,$$

although without knowing the rate of this convergence.

The next result expresses the modulus of continuity (in the time variable) for $Y$ and $Z$.

**Theorem 3.5** (Path regularity). Let (HX0), (HY0_{loc}) hold. Then the unique solution $(X, Y, Z)\in S^p \times S^p \times \mathcal{H}^p$ for all $p \geq 2$. Moreover,

(i) for any $p \geq 2$ there exists a constant $C_p > 0$ such that for $0 \leq s \leq t \leq T$ we have

$$\mathbb{E}\left[\sup_{s \leq u \leq t} |Y_u - Y_s|^p\right] \leq C_p(1 + |x|^p)|t - s|^\frac{p}{2}; \quad (3.26)$$

(ii) for any $p \geq 2$ there exists a constant $C_p > 0$ such that for any partition $\pi$ of $[0, T]$ with mesh size $|\pi|$ we have

$$\sum_{i=0}^{N-1} \mathbb{E}\left[\left(\int_{t_i}^{t_{i+1}} |Z_t - Z_{t_i}|^2 dt\right)^\frac{p}{2} + \left(\int_{t_i}^{t_{i+1}} |Z_t - Z_{t_{i+1}}|^2 dt\right)^\frac{p}{2}\right] \leq C_p(1 + |x|^p)|\pi|^{\frac{p}{2}}, \quad (3.27)$$

(iii) in particular, there exists a constant $C$ such that for any partition $\pi = \{0 = t_0 \leq \cdots \leq t_N = T\}$ of the interval $[0, T]$ with mesh size $|\pi|$ we have

$$\text{REG}_\pi(Y)^2 := \max_{0 \leq i \leq N-1} \sup_{t \in [t_i, t_{i+1})} \left\{\mathbb{E}\left[|Y_t - Y_{t_i}|^2\right] + \mathbb{E}\left[|Y_t - Y_{t_{i+1}}|^2\right]\right\} \leq C|\pi|,$$

and $\sum_{i=0}^{N-1} \mathbb{E}\left[\int_{t_i}^{t_{i+1}} |Z_t - \bar{Z}_{t_i}|^2 ds\right] \leq C|\pi|$. Moreover, if $r_\pi$ remains bounded\(^4\) as $|\pi| \to 0$ then

$$\text{REG}_\pi(Z)^2 := \sum_{i=0}^{N-1} \mathbb{E}\left[\int_{t_i}^{t_{i+1}} |Z_s - Z_{t_i}|^2 ds\right] + \sum_{i=0}^{N-1} \mathbb{E}\left[\int_{t_i}^{t_{i+1}} |Z_s - Z_{t_{i+1}}|^2 ds\right] \leq C|\pi|.$$

*Proof.* Fix $(t, x) \in [0, T] \times \mathbb{R}^d$, take $s \in [t, T]$ and throughout this proof we work with $\Theta_t^y$ and $\nabla_x \Theta_t^{y,x}$; to avoid a notational overload we omit the super- and subscript and write $\Theta$ and $\nabla \Theta$. Under the Theorem’s assumptions, $(X, Y, Z) \in S^p \times S^p \times \mathcal{H}^p$ for all $p \geq 2$ and (3.20) holds. We first prove point (i) and (ii) under Assumption (HXY1), then we use the same mollification argument as in the proof of (3.20) to recover the case (HX0)-(HY0_{loc}). We then explain how (iii) is obtained.

*Proof of (i) under (HXY1):* From Theorem 3.4 follows $Z \in S^q$ for any $q \geq 2$. Writing the BSDE for the difference $Y_u - Y_s$ for $0 \leq s \leq u \leq T$ we have

$$Y_u - Y_s = \int_s^u f(r, \Theta_r)dr - \int_s^u Z_r dW_r \leq \int_s^u K(1 + |X_r| + |Y_r| + |Z_r|) dr - \int_s^u Z_r dW_r.$$

\(^4\)This is trivially satisfied for the uniform grid for which $r_\pi = 1$. 

15
Applying BDG to the last term in the RHS then (3.20) yields

\[ \mathbb{E}\left[ \sup_{u \in [s,t]} |Y_u - Y_s|^p \right] \leq C_p \left\{ |t-s|^p (1 + \| (X,Y,Z) \|^p_{SP_x,SP_y,SP_z}) + \mathbb{E}\left[ \sup_{u \in [s,t]} \left| \int_s^u Z_r dW_r \right|^p \right] \right\}. \]

Applying BDG to the last term in the RHS then (3.20) yields

\[ \mathbb{E}\left[ \sup_{u \in [s,t]} \left| \int_s^u Z_r dW_r \right|^p \right] \leq C_p \mathbb{E}\left[ \left( \int_s^t |Z_r|^2 dr \right)^{\frac{p}{2}} \right] \leq C_p \left( \int_s^t (1 + X_r)^2 dr \right)^{\frac{p}{2}} \leq C_p |t-s|^p \| X \|^p_{SP}. \]

It then follows that

\[ \mathbb{E}\left[ \sup_{u \in [s,t]} |Y_u - Y_s|^p \right] \leq C_p \left\{ |t-s|^p + |t-s|^\frac{p}{2} \right\} \leq C_p (1 + |x|^p) |t-s|^\frac{p}{2}. \]

**Proof of (ii) under (HXY1):** To prove the desired inequality we use the representation (3.15) (alternatively (3.19)). We first estimate the difference \( \mathbb{E}[\left( \int_{t_i}^{t_{i+1}} |Z_s - Z_{t_i}|^2 ds \right)^{p/2}] \). The difference \( Z_s - Z_{t_i} \) can be written as \( Z_s - Z_{t_i} = I_1 + I_2 \) with \( I_2 := (\nabla Y_s - \nabla Y_{t_i}) (\nabla X_{t_i})^{-1} \sigma(t_i, X_{t_i}) \) and

\[
I_1 := \nabla Y_s \left\{ \left( (\nabla X_s)^{-1} - (\nabla X_{t_i})^{-1} \right) \sigma(s, X_s) + (\nabla X_{t_i})^{-1} \sigma(s, X_s) - \sigma(t_i, X_{t_i}) \right\}. \]

The estimation of \( I_1 \) is rather easy as it relies on Hölder’s inequality combined with (3.2), (HX0), Theorems 2.3 and 2.4 in [IDR10b] (see proof of Theorem 5.5(ii) in [IDR10b]), in short we have

\[ \mathbb{E}[|I_1|^p] \leq C_p (1 + |x|^p) |t-s|^\frac{p}{2}. \]

Concerning the second part, the estimation of \( I_2 \), it follows from an adaptation of the proof of Theorem 5.5(ii) in [IDR10a]. We reformulate the main argument and skip the obvious details. Let us start with a simple trick, as \( s \in [t_i, t_{i+1}] \),

\[ \mathbb{E}\left[ |(\nabla Y_s - \nabla Y_{t_i}) (\nabla X_{t_i})^{-1} \sigma(t_i, X_{t_i})|^p \right] \]

\[ = \mathbb{E}\left[ \mathbb{E}\left[ |(\nabla Y_s - \nabla Y_{t_i})|^p |(\nabla X_{t_i})^{-1} \sigma(t_i, X_{t_i})|^p \right| \mathcal{F}_t \right]. \]

Writing the BSDE for the difference \( \nabla Y_s - \nabla Y_{t_i} \) for \( t_i \leq s \leq t_{i+1} \) we have for some constant \( C > 0 \)

\[ \mathbb{E}\left[ |\nabla Y_s - \nabla Y_{t_i}|^p |\mathcal{F}_t \right] \leq C \mathbb{E}\left[ \hat{I}_{[t_i,t_{i+1}]} |\mathcal{F}_t \right] \]

where \( \hat{I}_{[t_i,t_{i+1}]} := \left( \int_{t_i}^{t_{i+1}} |(\nabla f)(r, \Theta_r)| |\nabla \Theta_r|^2 dr \right)^p + \left( \int_{t_i}^{t_{i+1}} |\nabla Z_r|^2 dr \right)^{2p/2} \),

where we used the conditional BDG inequality and maximized over the time interval \( [t_i, t_{i+1}] \).

Combining these last two inequalities and observing that since \( \nabla X_{t_i} \) and \( \sigma(X_{t_i}) \) are \( \mathcal{F}_{t_i} \)-adapted we can drop the conditional expectation from (3.28). Hence, for some \( C > 0 \),

\[
\sum_{i=0}^{N-1} \mathbb{E}\left[ \left( \int_{t_i}^{t_{i+1}} |I_2|^2 ds \right)^{\frac{p}{2}} \right] \leq C |\pi|^\frac{p}{2} -1 \sum_{i=0}^{N-1} \int_{t_i}^{t_{i+1}} \mathbb{E}[|I_2|^p] ds \]

\[ \leq C |\pi|^\frac{p}{2} -1 \sum_{i=0}^{N-1} \mathbb{E}\left[ |(\nabla X_{t_i})^{-1} \sigma(t_i, X_{t_i})|^p \hat{I}_{[t_i,t_{i+1}]} \right] \]

\[ \leq C |\pi|^\frac{p}{2} \mathbb{E}\left[ \sup_{0 \leq t \leq T} |(\nabla X_t)^{-1} \sigma(t, X_t)|^p \sum_{i=0}^{N-1} \hat{I}_{[t_i,t_{i+1}]} \right] \]

\[ \leq C |\pi|^\frac{p}{2} \| (\nabla X)^{-1} \|_{S_{3p}} \| 1 + X \|_{S_{3p}} \| \hat{I}_{[0,T]} \|_{L^1} \leq C (1 + |x|^p) |\pi|^\frac{p}{2}. \]
The last line follows from standard inequalities (sum of powers is less than the power of the sum), the growth conditions on \( \nabla f \) and the fact that for any \( q \geq 2 \) we have: \( X, \nabla X, (\nabla X)^{-1} \in S^q, Y, \nabla Y \in S^q, (3.20) \) and \( \nabla Z \in H^q \).

Collecting now the estimates we obtain the desired result for the difference \( Z_n - Z_{t_1} \). To have the same estimate for the difference \( Z_n - Z_{t_{i+1}} \) we need only to repeat the above calculations with a minor change in order to incorporate the \( I_1^{i+1} \) and \( I_2^{i+1} \), which are \( I_1 \) and \( I_2 \) respectively but with \( t_{i+1} \) instead of \( t_i \). The estimate for \( I_1^{i+1} \) follows from SDE theory in the same fashion as for \( I_1 \) above; concerning \( I_2^{i+1} \) one just needs another small trick,

\[
I_2^{i+1} = (\nabla Y_{t_{i+1}} - \nabla Y_{t_{i+1}}) (\nabla X_{t_{i+1}})^{-1} \sigma(t_{i+1}, X_{t_{i+1}})
\]

\[
\leq (|\nabla Y_{t_{i+1}}| + |\nabla Y_{t_{i+1}}|) (\nabla X_{t_{i+1}})^{-1} \sigma(t_{i+1}, X_{t_{i+1}}) - (\nabla X_{t_i})^{-1} \sigma(t_i, X_t)
\]

(3.29)

\[
+ (\nabla Y_{t_{i+1}} - \nabla Y_{t_{i+1}}) (\nabla X_{t_{i+1}})^{-1} \sigma(t_{i+1}, X_{t_{i+1}})
\]

(3.30)

The rest of the proof follows just like before, like \( I_1 \) for (3.29) and like \( I_2 \) for (3.30).

Final step - (i) and (ii) under (HX0)-(HY0loc) - arguing via mollification: here we follow the same setup as in the proof of (3.20) under (HX0)-(HY0loc) (see Theorem 3.4).

Take \( b^n, \sigma^n, g^n, f^n \) as mollified versions of \( b, \sigma, g, f \) in their spatial variables such that the mollified functions satisfy uniformly (in \( n \)) (HX0) and (HY0loc), with uniform Lipschitz and monotonicity constant. From the proof of Theorem 3.4, we know that \( \Theta = (X^n, Y^n, Z^n) \in S^{p} \times S^{p} \times H^{p} \) for any \( p \geq 2 \) and \( \Theta_n \rightarrow \Theta \) as \( n \rightarrow \infty \) in \( S^{p} \times S^{p} \times H^{p} \) for all \( p \geq 2 \).

For each \( n \in \mathbb{N} \) estimates (3.26) and (3.27) hold for \( \Theta^n \). Since \( b^n, \sigma^n, g^n, f^n \) satisfy (HX0) and (HY0loc) uniformly in \( n \) then it is easy to check that the constants appearing on the RHS of (3.26) and (3.27) are independent of \( n \). Hence, by taking the limit of \( n \rightarrow \infty \) in (3.26) and (3.27) and given the convergence \( \Theta^n \rightarrow \Theta \) as \( n \rightarrow \infty \) (and the continuity of the involved functions) the statement follows.

Proof of (iii) under (HX0)-(HY0loc): The estimates concerning \( Y \) and \( \bar{Z}_t \) follow trivially from (3.26) on the one hand, and (3.27) combined with (3.25) on the other hand. For the difference \( Z_n - \bar{Z}_{t_{i+1}} \) more care is required,

\[
\sum_{i=0}^{N-1} \mathbb{E} \left[ \int_{t_i}^{t_{i+1}} |Z_n - \bar{Z}_{t_{i+1}}|^2 ds \right] \leq 2 \sum_{i=0}^{N-1} \mathbb{E} \left[ \int_{t_i}^{t_{i+1}} |Z_n - Z_{t_{i+1}}|^2 + |Z_{t_{i+1}} - \bar{Z}_{t_{i+1}}|^2 ds \right]
\]

\[
\leq C|\pi| + 2 \sum_{i=0}^{N-1} (t_{i+1} - t_i) \mathbb{E} \left[ |Z_{t_{i+1}} - \bar{Z}_{t_{i+1}}|^2 \right],
\]

where the last inequality follows from the proof of (ii). We next estimate the last term in the RHS, since \( \bar{Z}_{t_N} = \bar{Z}_T \) by construction

\[
\sum_{i=0}^{N-1} (t_{i+1} - t_i) \mathbb{E} \left[ |Z_{t_{i+1}} - \bar{Z}_{t_{i+1}}|^2 \right] = \sum_{i=0}^{N-2} (t_{i+1} - t_i) \mathbb{E} \left[ |Z_{t_{i+1}} - \bar{Z}_{t_{i+1}}|^2 \right]
\]

\[
\leq r \sum_{i=0}^{N-2} (t_{i+2} - t_{i+1}) \mathbb{E} \left[ |Z_{t_{i+1}} - \bar{Z}_{t_{i+1}}|^2 \right] \leq r \sum_{i=0}^{N-2} \int_{t_{i+1}}^{t_{i+2}} \mathbb{E} \left[ |Z_{t_{i+1}} - \bar{Z}_{t_{i+1}}|^2 \right] ds
\]

\[
\leq r \sum_{j=1}^{N-1} \int_{t_j}^{t_{j+1}} \mathbb{E} \left[ |Z_{t_j} - \bar{Z}_{t_j}|^2 \right] ds \leq 2r \sum_{i=0}^{N-1} \mathbb{E} \left[ \int_{t_i}^{t_{i+1}} |Z_n - Z_t|^2 + |Z_n - \bar{Z}_t|^2 ds \right],
\]

where we made use of the assumption on the grid. The result now follows by combining (iii) with the above estimates and having in mind that \( r \) is uniform over the partition. □
Corollary 3.6. Let \((HX0), (HY0)\) hold and take the family \(\{\bar{Z}_t\}_{t_i \in \pi}\). For any \(p \geq 1\) there exists constant \(C_p\) independent of \(|\pi|\) such that
\[
E\left[ \sum_{i=0}^{N-1} \left( |\bar{Z}_{t_{i+1} - t_i}|^p \right) \right] \leq C_p < \infty.
\]
If, moreover, \((HY0_{loc})\) holds then \(\max_{t_i \in \pi} E[|\bar{Z}_{t_i}|^{2p}] \leq C_p < \infty\).

Proof. The second statement follows easily from the definition of \(\bar{Z}_t\) (see (3.23)) and the fact that estimate (3.20) holds under \((HY0_{loc})\). Moreover, under this assumption the second estimate implies the first.

We leave the proof of the first statement for the interested reader. The proof is based on standard integral manipulations combining the definition of \(\bar{Z}_t\), Jensen's inequality, the fact that \(Z \in \mathcal{H}^p\) and the tower property of the conditional expectation (see Section 4.7.5 in [Lio14]). \(\square\)

3.5 Some finer properties

Here we discuss properties of the solution to (1.1)-(1.2) in more specific settings. The first lemma concerns a set-up where \(Z\) belongs to \(\mathcal{S}^\infty\) (rather than \(\mathcal{H}^2\) or \(\mathcal{S}^2\)).

Proposition 3.7 (The additive noise case). Let \((HX0)-(HY0_{loc})\) hold. Assume additionally that \(\sigma(t,x) = \sigma(t)\) for all \((t,x) \in [0,T] \times \mathbb{R}^d\). Then \(Z \in \mathcal{S}^\infty\).

Proof. Assume first that \((HXY1)\) also hold. Then the result follows easily by combining the representation formula (3.18) with the 2nd part of (3.3) and injecting that \(\sigma\) is uniformly bounded.

Now using a standard mollification argument, as was used in the last step of the proof of Theorem 3.5, one easily concludes that the result also holds under \((HX0)-(HY0_{loc})\). \(\square\)

If the initial data \(g\) and \(f(\cdot,\cdot,0,0)\) are bounded then so will be the \(Y\) process; the second component, \(Z\) will also satisfy a type of boundedness condition (see (3.31) below).

Lemma 3.8 (The bounded setting). Let \((HX0), (HY0)\) hold and further that \(g\) and \((t,x) \mapsto f(t,x,0,0)\) are uniformly bounded then \((Y,Z) \in \mathcal{S}^\infty \times \mathcal{H}^2\).

Denoting \(\mathcal{T}_{[0,T]}\) the set of all stopping times \(\tau \in [0,T]\), then \(Z\) satisfies further\footnote{This means \(Z\) belongs to the so called \(\mathcal{H}^{BMO}\)-spaces, see Subsection 2.3 in [IDR10b] or Section 10.1 in [Tou12].} for some constant \(K_{BMO} > 0\)
\[
\sup_{\tau \in \mathcal{T}_{[0,T]}} \left\| E\left[ \int_{\tau}^{T} |Z_s|^2 ds |\mathcal{F}_\tau| \right] \right\|_{\infty} \leq K_{BMO} < \infty. \quad (3.31)
\]

The constant \(K_{BMO}\) depends only on \(\|Y\|_{\mathcal{S}^\infty}\), the bounds for \(g, f(\cdot,\cdot,0,0)\) and the constants appearing in \((HY0)\).

Proof. The boundedness of \(Y\) follows from (2.5) by using that \(g(X), f(\cdot,X,0,0) \in \mathcal{S}^\infty\). Knowing that \(Y \in \mathcal{S}^\infty\) we can easily adapt the proof of Lemma 10.2 in [Tou12] to our setting, where we make use of the inequality \(|z| \leq 1 + |z|^2\), to obtain (3.31); an alternative proof would be to use (2.5). \(\square\)

The first of the above results implies that \(Z\) is bounded. Such a setting also includes the case of \(\sigma(t,x) = 1\) which is common in many applications in reaction-diffusion equations. The next result provides another type of control for the growth of the process \(Z\) without the boundedness assumption on \(\sigma\).
that $|Z|^2$ is a sub-martingale then $|Z_t|^2 \leq K_{BMO}/\sqrt{T-t}$, $\forall t \in [0,T]$ $\mathbb{P}$-a.s.

In particular, if $\sigma$ is uniformly elliptic and $(HXY1)$ holds then there exists $C > 0$ such that $|\nabla_x u(t,x)| \leq C/\sqrt{T-t}$, $\forall (t,x) \in [0,T) \times \mathbb{R}^d$.

Proof. The first statement follows by a careful but rather clean analysis of the fact that $Z$ satisfies (3.31), which in particular means any $t \in [0,T]$ $\mathbb{P}$-a.s.

$$K_{BMO} \geq \mathbb{E}\left[\int_t^T |Z_s|^2 ds | \mathcal{F}_t\right] = \int_t^T \mathbb{E}\left[|Z_s|^2 | \mathcal{F}_t\right] ds \geq \int_t^T |Z_t|^2 ds = |Z_t|^2(T-t),$$

where we applied Fubini then used the sub-martingale property of $Z^2$. The sought statement now follows by a direct rewriting of the above inequality. The second statement in the proposition follows from the first by using the representation $Z_t^{xx} = (\nabla_x u\sigma)(t,x)$ and the ellipticity of $\sigma$. \qed

4 Numerical discretization and general estimates.

In this section and the following ones, we discuss the numerical approximation of (1.1)-(1.2). We consider a regular partition of $[0,T]$ with $N + 1$ points $t_i = ih$ for $i = 0, \cdots, N$ with $h := T/N$.

Remark 4.1 (On constants). Throughout the rest of this work we introduce a generic constant $c > 0$, that will always be independent of $h$ or $N$, though it may depend on the problem’s data, namely the constants appearing in the assumptions, and may change from line to line.

4.1 Discretization of the SDE and further setup

Numerical methods for SDEs with Lipschitz continuous coefficients are well understood, see Section 10 in [KP92]. Therefore, we take as given a family of random variables $\{X_i\}_{i=0,\ldots,N}$ that approximates the solution $X$ to (1.1) over the grid $\pi$. More exactly, for any $p \geq 2$ there exists a constant $c = c(T,p,x)$ such that

$$\sup_{N \in \mathbb{N}} \max_{i=0,\ldots,N} \mathbb{E}\left[|X_i|^p\right] \leq c \quad \text{and} \quad \text{ERR}_{\pi,p}(X) := \max_{i=0,\ldots,N} \mathbb{E}\left[|X_t - X_i|^p\right]^{\frac{1}{p}} \leq c h^{\gamma}, \quad \gamma \geq \frac{1}{2}, \quad (4.1)$$

where $\gamma$ is called the rate of the strong convergence and the random variables $\{X_i\}_{i \in \pi}$ are the solution to (1.1) on the grid points $\pi$. Under (HX0) the Euler scheme give an approximation with $\gamma = 1/2$. For conditions required for the higher order schemes we refer to [KP92]. Since the upper bound in the estimate on the error on $X$ does not depend on $p$, and since we use only the case $p = 2$ in the following, we simplify the notation to $\text{ERR}_{\pi}(X) \leq c h^{\gamma}$.

Throughout the rest of this work we assume that the family $\{X_i\}_{i=0,\ldots,N}$ has been computed; we denote by $\{\mathcal{F}_i\}_{i=0,\ldots,N}$ the associated discrete-time filtration $\mathcal{F}_i := \sigma(X_j, j = 0, \cdots, i)$ and with respect to this filtration we define the operator $\mathbb{E}[-] := \mathbb{E}[-|\mathcal{F}_i]$.

For the analysis of the time-discretization error, we also make use of the following standard path-regularity estimate for $X$, which holds under (HX0): there exists a constant $c > 0$ such that

$$\text{REG}_{\pi}(X) := \max_{i=0,\ldots,N-1} \sup_{t_i \leq s \leq t_{i+1}} \left\{ \mathbb{E}\left[|X_s - X_i|^2\right]^{\frac{1}{2}} + \mathbb{E}\left[|X_s - X_{i+1}|^2\right]^{\frac{1}{2}} \right\} \leq c h^{\frac{1}{2}}, \quad (4.2)$$

6 We point out that the results we state would hold for non-uniform time-steps, but we work with a regular partition for notational clarity and to keep the focus on the main issues.
4.2 Schemes considered and main convergence results

For the reader’s convenience we state immediately the numerical schemes under consideration as well as their convergence rates. The rest of this work deals with the proofs of the stated results.

Theorem 3.5 implies that to approximate \((Y,Z)\) solution to (1.2) over \([0,T]\) one needs only to approximate the family \(\{(Y_i,Z_i)\}_{i\in\pi}\) (recall (3.23)) on the grid \(\pi\) via a family of random variables \(\{(Y_i,Z_i)\}_{i=0,\ldots,N}\), the said numerical approximation. The error criterion we consider is given by

\[
\text{ERR}_\pi(Y,Z) := \left( \max_{i=0,\ldots,N} \mathbb{E}[|Y_i - Y|^2] + \sum_{i=0}^{N-1} \mathbb{E}[|Z_i - Z_i|^2]h \right)^{1/2}.
\] (4.3)

4.2.1 The implicit-dominant \(\theta\)-schemes of Section 5

Let \(\theta \in [0,1]\). Define \(Y_N := g(X_N)\) and \(Z_N := 0\) and, for \(i = N-1, N-2, \ldots, 0\),

\[
Y_i := E_i \left[ Y_{i+1} + (1-\theta)f(t_{i+1}, X_{i+1}, Y_{i+1}, Z_{i+1})h \right] + \theta f(t_i, X_i, Y_i, Z_i)h,
\] (4.4)

\[
Z_i := E_i \left[ \frac{\Delta W_{i+1}}{h} \left( Y_{i+1} + (1-\theta)f(t_{i+1}, X_{i+1}, Y_{i+1}, Z_{i+1})h \right) \right],
\] (4.5)

where \(\Delta W_{i+1} = W_{i+1} - W_i\). The above scheme is the called \(\theta\)-scheme. Its derivation is presented in Subsection 4.4 and the solvability (in \(Y_i\)) of (4.4) for \(\theta > 0\) is discussed in Subsection 4.5. When \(\theta = 1\) this is the implicit backward Euler scheme, when \(\theta = 0\) this is the explicit scheme. For \(\theta \in ]0,1[\) it is a combination of both. The particular case of \(\theta = 1/2\) is the trapezoidal scheme which, we will show, has a better convergence rate (under certain conditions). The convergence rate of the above scheme is summarized in the next result.

Theorem 4.2. Let \((HX0), (HY0_{loc})\) hold and \(h \leq \min\{\frac{1}{4\theta(L_y + 3\theta L_z^2)}, 1\}\). Let \(\gamma \geq 1/2\) be the order of the approximation \(\{X_i\}_{i=0,\ldots,N}\) of \(X\) as in (4.1). Then, for the scheme (4.4)-(4.5) we have:

i) For \(\theta \in ]1/2,1[\), there exists a constant \(c\) such that \(\text{ERR}_\pi(Y,Z) \leq ch^{1/2}\).

ii) Take \(\theta = 1/2\) and scheme (4.4). Assume that \(f \in C^2\), \(f(t, x, y, z) = f(y)\) and \(\partial_{yy}^2 f\) has at most polynomial growth, then there exists \(c > 0\) such that \(\max_{i=0,\ldots,N} \mathbb{E}[|Y_i - Y_i|^2]^{1/2} \leq ch^{\min\{7/4, \gamma\}}\).

Reasons why the above theorem only holds for \(\theta \geq 1/2\) — that is to say when the scheme is “more implicit than explicit” — will be seen later, in the proofs in Section 5. But from the motivating example of the Introduction, we know already that one could not have expected convergence of the scheme in general, for all \(\theta \in [0,1]\).

4.2.2 The tamed explicit scheme of Section 6

By inspecting the proof of Lemma A.2 we see that the unboundedness of \(g(X_T)\) plays the key role in the explosion. In Section 6 we analyze a tamed version of the fully explicit \((\theta = 0)\) scheme (4.4)-(4.5).

For any level \(L > 0\), we define the truncation function \(T_L : \mathbb{R} \to \mathbb{R}, x \mapsto -L \vee x \wedge L\). We denote similarly its extension as a function from \(\mathbb{R}^d\) to \(\mathbb{R}^d\) (projection on the ball of radius \(L\)). We consider the following scheme: define \(Y_N := T_{L_N}(g(X_N))\), \(Z_N := 0\), and for \(i = N-1, \ldots, 0\),

\[
Y_i := E_i \left[ Y_{i+1} + f(t_{i+1}, T_{K_h}(X_{i+1}), Y_{i+1}, Z_{i+1})h \right],
\] (4.6)

\[
Z_i := E_i \left[ \frac{\Delta W_{i+1}}{h} \left( Y_{i+1} + f(t_{i+1}, T_{K_h}(X_{i+1}), Y_{i+1}, Z_{i+1})h \right) \right],
\] (4.7)
where the levels $L_h$ and $K_h$ satisfy $e^{c_1 T}(L_h^2 + c_2 T + c_2 TK_h^2) \leq h^{-1/(m-1)}$, with

$$c_1 = 2(L_y + 12dL_z^2 + 2L_y^2) \quad \text{and} \quad c_2 = \max \left\{ \frac{L_z^2}{4dL_z^2}, \frac{L_y^2}{4dL_z^2} \right\}.$$  

For $h \leq h^*$, where $h^*$ satisfies $e^{c_1 T}c_2 T \leq (h^*)^{-1/(m-1)}/3$ and $h^* \leq 1/(32dL_z^2)$ we can take

$$L_h = \frac{1}{\sqrt{3}} e^{-\frac{1}{2}c_1 T} \left( \frac{1}{h} \right)^{\frac{1}{2(m-1)}}, \quad \text{and} \quad K_h = \frac{1}{\sqrt{3}} \frac{e^{-\frac{1}{2}c_1 T} \left( \frac{1}{h} \right)^{\frac{1}{2(m-1)}}}{\sqrt{c_2 T}}.$$ 

Concerning the scheme (4.6)-(4.7) we have the following convergence rate.

**Theorem 4.3.** Let $(HX_0), (HY_{0,loc})$ hold and $h \leq h^*$. Assume that the order $\gamma$ of the approximation $\{X_i\}_{i=0,\ldots,N}$ of $X$ is at least $1/2$ (see (4.1)). Then for the controlled explicit scheme (4.6)-(4.7), there exists a constant $c$ such that $\text{ERR}_\pi(Y,Z) \leq c h^{1/2}$.

4.2.3 **Modus operandi for the proofs and organization of rest of the paper**

The proof of the above results is a (long) two-step procedure. The first step is contained in the rest of this section since it is a general argument common to most discretization schemes. The second one is scheme-specific, hence the separation into Section 5 and Section 6. We now describe the said procedure.

Before one is able to state a global error estimate for (4.3), one needs to find the local error estimates, i.e. the distance between the solution and its approximation over one time interval $[t_i, t_{i+1}]$. This local error has two components. The first is the one-step discretization error following from approximating the involved integrals over $[t_i, t_{i+1}]$ by some quadrature rule. The second is the backward propagation of the error due to not having at time $t_{i+1}$ the true solution to compute the approximation at time $t_i$ and we coin it stability error.

In the next subsection we give the Fundamental Lemma for convergence (Lemma 4.6) that explains how to aggregate the one-step discretization error and the stability error for each $[t_i, t_{i+1}]$ into a single estimate with (4.3) on its LHS. This later allows to derive the convergence rates.

The estimation of the one-step discretization error is common to both schemes. This is done in Subsection 4.6 and the general result is stated in Proposition 4.13. Left to Sections 5 and 6 is the scheme-specific stability analysis (i.e. the estimation of $\mathcal{R}^S(H)$ in (4.10) below). Sections 5 and 6 follow the same structure: 1) one first shows some uniform global integrability for the scheme; 2) then one studies the local (one-step) stability of the scheme; this shows how the error propagates in just one backward step, and yields an expression for the terms $H_j$ composing the stability remainder (see Definition 4.4 below); 3) one finally estimates the stability remainder $\mathcal{R}^S(H)$. Once this is done, one can inject the results into estimate (4.10) given by the Fundamental Lemma 4.6; and finally estimate the RHS of (4.10) as a function of the time-step $h$, hence obtaining the convergence rate.

At the end of Section 5 we discuss the fully 2nd-order discretization scheme when $f$ is allowed to depend only on $y$ and we discuss as well a variance reduction trick for the computation of the involved conditional expectations.

4.3 **Fundamental lemma for convergence**

The goal of this section is to present a very general but clear result estimating the global error (4.3) of a scheme for BSDE (1.2). Although this type of analysis has already been used in the context of Lipschitz BSDEs (see e.g. [CM12], [Cha12] or [Cha13]), we generalize it to the non-Lipschitz
framework we are working with. More precisely, the Fundamental Lemma we present below allows us to cope with schemes which lack stability in the sense of \cite{Cha13}.

### 4.3.1 Abstract formulation of a scheme and description of the local error

In abstract terms, a discretization scheme for a BSDE generates recursively (and backward in time) a family of random variables $\{(Y_i, Z_i)\}_{i=0,\ldots,N}$ approximating $\{(Y_t, Z_t)\}_{t<\pi}$ via some operators $\Phi_i : L^2(F_{i+1}) \times L^2(F_{i+1}) \to L^2(F_i) \times L^2(F_i)$, $i \in \{N-1, \ldots, 0\}$. One starts with an initial approximation $(Y_N, Z_N)$ and for $i = N-1, \ldots, 0$ computes $(Y_i, Z_i) := \Phi_i(Y_{i+1}, Z_{i+1})$. (Compare with (4.4)-(4.5) or (4.6)-(4.7).

Since $(Y_i, Z_i)$ is obtained via $\Phi_i$ from the input $(Y_{i+1}, Z_{i+1})$ we introduce the following notation: for any $i = 0, 1, \ldots, N-1$, given a $F_{i+1}$-measurable input $(Y', Z')$, the pair $(Y_i(Y', Z'), Z_i(Y, Z))$ denotes the associated output of $\Phi_i(Y, Z)$. Writing $(Y_i, Z_i)$ without specifying the input denotes the canonical output of $\Phi_i(Y_{i+1}, Z_{i+1})$, that is, we refer to the family of RV’s $\{(Y_i, Z_i)\}_{i=0,\ldots,N}$. We introduce as well the notation $\hat{Y}_i = Y_i(Y_{i+1}, Z_{i+1})$ and $\hat{Z}_i = Z_i(Y_{i+1}, Z_{i+1})$ as the output of $\Phi_i(Y_{i+1}, Z_{i+1})$.

We decompose the local error into two parts: the one-step time-discretization error and the propagation to time $t_i$ of the error from time $t_i+1$ (the stability error). So given $i \in \{0, \ldots, N-1\}$ we write

\[ Y_i = Y_i(Y_{i+1}, Z_{i+1}) + \hat{Y}_i - Y_i \]

\[ Z_i = Z_i(Y_{i+1}, Z_{i+1}) + \hat{Z}_i - Z_i \]

and similarly for $Z$

We now turn to the question of how to aggregate these errors in order to estimate the global error $\text{ERR}_\pi(Y, Z)$ (see (4.3)).

### 4.3.2 The fundamental stability Lemma

The purpose of the Fundamental Lemma below is to formulate in a transparent way the ingredients required to show convergence of $\{(Y_i, Z_i)\}_{i=0,\ldots,N}$ to $\{(Y_t, Z_t)\}_{t<\pi}$ in the error criterion (4.3). To start with, we define precisely our concept of stability, generalizing that in \cite{Cha12} and \cite{Cha13}.

**Definition 4.4 (Scheme stability).** We say that the numerical scheme $\{(Y_i, Z_i)\}_{i=0,\ldots,N}$ is stable if for some $\rho > 0$ there exists a constant $c > 0$ such that

\[
\mathbb{E}[|Y_i(Y_{i+1}, Z_{i+1}) - Y_i(Y_{i+1}, Z_{i+1})|^2] + \rho \mathbb{E}[|Z_i(Y_{i+1}, Z_{i+1}) - Z_i(Y_{i+1}, Z_{i+1})|^2]h \\
\leq (1 + ch) \left( \mathbb{E}[|Y_{i+1} - Y_{i+1}|^2] + \frac{\rho}{4} \mathbb{E}[|Z_{i+1} - Z_{i+1}|^2]h \right) + \mathbb{E}[H_i],
\]

\[(4.8)\]

\text{See definition 2.1 in \cite{Cha13} with } \gamma_i^Y = \gamma_i^Z = 0 \text{ for } i = 0, \ldots, N-1.

22
where \( H_i \in L^1(\mathcal{F}_i) \) and moreover \( \{H_i\}_{i=0,\ldots,N-1} \) satisfies

\[
\mathcal{R}^S(H) := \max_{i=0,\ldots,N-1} \sum_{j=i}^{N-1} e^{(j-i)h} E[H_j] \to 0, \quad \text{as} \quad h \to 0.
\]

The quantity \( \mathcal{R}^S(H) \) is called the stability remainder.

**Remark 4.5.** In the case where \( f \) is a globally Lipschitz function, it can be shown for both implicit and explicit schemes that \( H_i = 0 \) (see [CM12] or [Cha13]). The scheme is then locally stable. Our definition of stability allows one to cope with schemes which are not locally stable, as is the case when \( f \) is a monotone function with polynomial growth in \( y \), provided we can control the term \( \mathcal{R}^S(H) \) (which we do in Section 5). We also point out that it is crucial that in (4.8) we have \( \rho > \frac{\pi}{2} \) (compare LHS with RHS). This later allows the use of Gronwall type inequalities (see Lemma A.4).

We now state the Fundamental Lemma which is the basis of the error analysis throughout.

**Lemma 4.6 (Fundamental Lemma).** Assume that the numerical scheme \( \{(Y_i, Z_i)\}_{i=0,\ldots,N} \) is stable. Denoting the one-step discretization errors for \( i = 0,\ldots,N-1 \) by

\[
\begin{align*}
\tau_i(Y) &:= E[|Y_i - Y_{i}(Y_{i+1},Z_{i+1})|^2] = E[|Y_i - \hat{Y}_i|^2] \\
\tau_i(Z) &:= E[|\hat{Z}_i - Z_{i}(Y_{i+1},Z_{i+1})|^2h] = E[|\hat{Z}_i - \hat{Z}_i|^2h],
\end{align*}
\]

there exists a constant \( C = C(\rho, T, c) \) such that

\[
(ERR_\pi(Y, Z))^2 \leq C\left\{ E[|Y_N - Y_N|^2] + E[|\hat{Z}_N - Z_N|^2h] + \sum_{i=0}^{N-1} \left( \frac{\tau_i(Y)}{h} + \tau_i(Z) \right) \right\} + (1 + h)\mathcal{R}^S(H). \tag{4.10}
\]

This result states in a rather clear fashion (although \( \mathcal{R}^S(H) \) is unknown at this point) what is required in order to have convergence of the numerical scheme. First, one needs a control on the approximation of the terminal conditions (the first two terms in the RHS of (4.10)). Second, one needs a control on the sum of the one-step time-discretization errors (4.9) (the 3rd term in the RHS of (4.10)). Third, one needs a control on the stability remainder \( \mathcal{R}^S(H) \) arising from the scheme stability (4.8) (last term in the RHS of (4.10)). Of course, the form of \( \mathcal{R}^S(H) \) depends on the specific scheme one is handling but in general the error \( ERR_\pi(Y, Z) \) of the scheme is always dominated by (4.10).

The first element will be estimated in Lemma 4.8. The second is the subject of Subsection 4.6 and the estimate is given in Proposition 4.13. Finally the study of the stability of the schemes is done in Sections 5 and 6. The convergence rate of the scheme will then follow by estimating further the RHS of (4.10).

**Proof.** We use throughout the notation \( \hat{Y}_i = Y_i(Y_{i+1},Z_{i+1}), \hat{Z}_i = Z_i(Y_{i+1},Z_{i+1}), Y_i = Y_i(Y_{i+1},Z_{i+1}) \) and \( Z_i = Z_i(Y_{i+1},Z_{i+1}) \) introduced in Subsection 4.3.1. We decompose the error as explained above and use Young’s inequality to get \( |Y_i - Y_i|^2 \leq (1 + \frac{1}{h})|Y_i - \hat{Y}_i|^2 + (1 + h)|Y_i - \hat{Y}_i|^2h \) and \( |\hat{Z}_i - Z_i|^2h \leq 2|\hat{Z}_i - \hat{Z}_i|^2h + 2|\hat{Z}_i - Z_i|^2h \).

Using \( \rho > 0 \) from (4.8) and the definition (4.9) above, it then follows that

\[
\begin{align*}
E[|Y_i - Y_i|^2] + \frac{\rho}{2} E[|\hat{Z}_i - Z_i|^2h] \\
\leq (1 + h)E[|\hat{Y}_i - Y_i|^2] + \rho E[|\hat{Z}_i - Z_i|^2h] + \left( (1 + \frac{1}{h})\tau_i(Y) + \rho\tau_i(Z) \right).
\end{align*}
\]
Since $\rho \leq (1 + h)\rho$, by the stability of the scheme (see (4.8)) it follows that

$$\mathbb{E}[|Y_{t_i} - Y_i|^2] + \rho^2 \mathbb{E}[|\tilde{Z}_{t_i} - Z_i|^2]h \leq (1 + h)(1 + ch)(\mathbb{E}[|Y_{t_{i+1}} - Y_{i+1}|^2] + \rho^2 \mathbb{E}[|\tilde{Z}_{t_{i+1}} - Z_{i+1}|^2]h)$$

$$+ \left((1 + \frac{1}{h})\tau_i(Y) + \rho\tau_i(Z) + (1 + h)\mathbb{E}[H_i]\right).$$

(4.11)

Taking $I_i := |Y_{t_i} - Y_i|^2 + \frac{\rho}{4}|\tilde{Z}_{t_i} - Z_i|^2h$ we have

$$\mathbb{E}[I_i] + \rho^2 \mathbb{E}[|\tilde{Z}_{t_i} - Z_i|^2]h \leq (1 + h)(1 + ch)\mathbb{E}[I_{i+1}] + \left((1 + \frac{1}{h})\tau_i(Y) + \rho\tau_i(Z) + (1 + h)\mathbb{E}[H_i]\right),$$

and we conclude the proof using Lemma A.4.

\[\square\]

### 4.4 Discretization of the BSDE

Let $t_i, t_{i+1} \in \pi$. To approximate the solution $(Y, Z)$ to (1.2) we need two approximations, one for the $Y$ component and one for the $Z$ component. Write (1.2) over the interval $[t_i, t_{i+1}]$ and take $\mathcal{F}_{t_i}$-conditional expectations to obtain (recalling that $\Theta_s = (X_s, Y_s, Z_s)$)

$$Y_{t_i} = \mathbb{E}_{t_i}[Y_{t_{i+1}} + \int_{t_i}^{t_{i+1}} f(s, \Theta_s)ds].$$

(4.12)

For the $Z$ component, one multiplies (1.2) (written over the interval $[t_i, t_{i+1}]$) by the Brownian increment, $\Delta W_{i+1} := W_{t_{i+1}} - W_{t_i}$, and takes $\mathcal{F}_{t_i}$-conditional expectations to obtain (using Itô’s isometry) the implicit formula

$$0 = \mathbb{E}_{t_i}[\Delta W_{i+1}(Y_{t_{i+1}} + \int_{t_i}^{t_{i+1}} f(s, \Theta_s)ds)] - \mathbb{E}_{t_i}[^{\int_{t_i}^{t_{i+1}}} Z_sds].$$

(4.13)

One now obtains a scheme by approximating the Lebesgue integral via the $\theta$-integration rule (indexed by a parameter $\theta \in [0, 1]$), i.e. for some function $\psi$

$$\int_{t_i}^{t_{i+1}} \psi(s)ds \approx [\theta\psi(t_i) + (1 - \theta)\psi(t_{i+1})](t_{i+1} - t_i), \quad \theta \in [0, 1].$$

This type of approximation of the integral is generally known to be of first order for $\theta \neq 1/2$ and of higher order for $\theta = 1/2$ (see end of this section). Unfortunately, with the results obtained so far (see Section 3) we are not able to prove the convergence of a general higher order approximation in its full generality; roughly, the issue boils down to obtaining controls on $|\partial^2_x \psi|$ where $\psi$ is solution to (2.9). However, under the results of Section 3, we do not even know if $\partial^2_x \psi$ exists. Under the assumption that $f$ is independent of $z$ we can prove that the scheme is indeed of higher order (in the $y$ component); the general case is left for future research.

From (4.13) above we have (compare with (3.23))

$$\tilde{Z}_{t_i} := \frac{1}{h} \mathbb{E}_{t_i}[^{\int_{t_i}^{t_{i+1}}} Z_sds] = \frac{1}{h} \mathbb{E}_{t_i}[\Delta W_{i+1}(Y_{t_{i+1}} + \int_{t_i}^{t_{i+1}} f(s, \Theta_s)ds)].$$

24
and we approximate \((Z_s)_{s\in [t_i, t_{i+1}]}\) via \(\bar{Z}_{t_i}\) and \(\bar{Z}_{t_{i+1}}\) rather than \(Z_{t_i}\) or \(Z_{t_{i+1}}\). Following the notation for \(\Theta\) we denote \(\Theta_{t_i} := (X_{t_i}, Y_{t_i}, \bar{Z}_{t_i})\) and using the \(\theta\)-integration rule it follows

\[
Y_{t_i} = \mathbb{E}_{t_i} \left[ Y_{t_{i+1}} + h \left[ \theta f(t_i, \Theta_{t_i}) + (1 - \theta)f(t_{i+1}, \Theta_{t_{i+1}}) \right] + \int_{t_i}^{t_{i+1}} R(s) ds \right], \tag{4.14}
\]

\[
Z_{t_i} = \mathbb{E}_{t_i} \left[ \frac{\Delta W_{i+1}}{h} Y_{t_{i+1}} + (1 - \theta)f(t_{i+1}, \Theta_{t_{i+1}})h + \int_{t_i}^{t_{i+1}} R(s) ds \right], \tag{4.15}
\]

where the error term is, for \(s \in [t_i, t_{i+1}]\), defined as \(R(s) := \theta R^I(s) + (1 - \theta)R^E(s)\) where

\[
R^I(s) := f(s, \Theta_s) - f(t_i, \Theta_{t_i}) \quad \text{and} \quad R^E(s) := f(s, \Theta_s) - f(t_{i+1}, \Theta_{t_{i+1}}). \tag{4.16}
\]

**Remark 4.7.** For the error analysis here and in the following section we always understand the set of RVs \(\{(Y_{t_i}, Z_{t_i})\}_{t_i \in \pi}\) as the true solution of the BSDE on the partition points \(t_i \in \pi\) but in the set-up of (4.14) and (4.15). We emphasize that our numerical scheme does not aim at approximating \(Z\) itself over \(\pi\) but the family \(\{Z_{t_i}\}_{t_i \in \pi}\).

The order of the approximation depends on the smoothness of driver \(f\) and the properties of the other coefficients. Ignoring the error term \(R\) we find the discretization scheme stated in (4.4)-(4.5). We point out that we aim at 1st order schemes, so setting \(Z_N = 0\) is not an issue. For a higher order schemes, \(Z_T\) needs to be approximated in a more robust fashion, e.g. following (3.24), \(Z_T = (\nabla_x g)(X_T)\sigma(T, X_T) \approx (\nabla_x g)(X_N)\sigma(T, X_N) = Z_N\) (under the extra assumption that \(\nabla g\) is Lipschitz).

We can already estimate the error on the terminal conditions, which is the first group of terms in the global error estimate from the Fundamental Lemma 4.6.

**Lemma 4.8.** Let \((HX0), (HY0)\) hold. Then there exists a constant \(c\) such that (recall (3.23))

\[
\mathbb{E}[|Y_{t_N} - Y_N|^p]^{\frac{1}{p}} \leq c h^\gamma \quad \text{for any} \quad p \geq 2 \quad \text{and} \quad \mathbb{E}[|\bar{Z}_{t_N} - Z_N|^2 h] \leq c h, \tag{4.17}
\]

where \(\gamma\) is the order of the approximation \(\{X_i\}_{i=0, \ldots, N}\) of \(X\) (according to (4.1)).

Assume that \(g \in C^1_b\) and that \(\nabla g\) is Lipschitz continuous. Define \(Z_N := (\nabla_x g)(X_N)\sigma(T, X_N)\) then \(\mathbb{E}[|\bar{Z}_{t_N} - Z_N|^2 h] \leq c h^2\).

**Proof.** The error estimate on \(Y_{t_N}\) results from the Lipschitz regularity of \(g\) and the estimate on \(\mathbb{E}[|X_{t_N} - X_N|^2]\) given by (4.1). For the error estimate on \(Z\), we have \(Z_N = 0\) and \(\bar{Z}_{t_N} = Z_T\), which in turn implies \(\mathbb{E}[|\bar{Z}_{t_N} - Z_N|^2 h] = \mathbb{E}[|Z_T|^2 h] \leq c h\) where we have used (3.24).

In the case where \(g \in C^1_b\) and \(\nabla g\) is Lipschitz, the estimate follows easily using that \(\bar{Z}_T = Z_T = \nabla g(X_T)\sigma(T, X_T)\) and using the Lipschitz property of \(\nabla g\) and \(\sigma\), Cauchy-Schwartz’ inequality and (4.1).

### 4.5 Existence and local estimates for the general \(\theta\)-scheme

In this subsection we start the study of the \(\theta\)-scheme (4.4)-(4.5) by analyzing one step of it, i.e. going from time \(t_{i+1}\) to \(t_i\). To simplify notation, we define \(f_{i+1} := f(t_{i+1}, X_{i+1}, Y_{i+1}, Z_{i+1})\) and \(A_{i+1} := Y_{i+1} + (1 - \theta)f_{i+1}h\).

Along with (HX0) and (HY0) we make the temporary assumption that \(Y_{i+1}, Z_{i+1}, f_{i+1} \in L^2\) (this integrability assumption is clearly satisfied by \(Y_N, Z_N\) and \(f_N\)) and analyze how, when \(\theta > 0\), this integrability carries on to the next time step.
Note that for $\theta = 0$ (i.e. the explicit case) the scheme step is well defined as $Y_i$ and $Z_i$ can be easily computed. For $\theta > 0$, there is no issue in defining $Z_i$ from (4.5), but unlike in the Lipschitz case, it is not immediate that the solution $Y_i$ to the implicit equation (4.4) exists. We need to show first that there exists a unique $Y_i$ solving $Y_i = \mathbb{E}_i[A_{i+1}] + \theta f(t_i, X_i, Y_i, Z_i)\omega_i$, where $\mathbb{E}_i[A_{i+1}], X_i$ and $Z_i$ are already known. This follows from Theorem 26.A in [Zei90] (p557). Define (almost surely) the map $F : y \mapsto y - \theta f(t_i, X_i(\omega), y, Z_i(\omega))\omega_i$. This map is strongly monotone (increasing) in the sense of Definition 25.2 in [Zei90], i.e. there exists a $\mu > 0$ such that for all $y, y'$,
\[
\langle y' - y, F(y') - F(y) \rangle \geq \mu \|y' - y\|^2.
\]
Indeed, from (HY0) and Remark 2.1 we have
\[
\langle y' - y, F(y') - F(y) \rangle \geq (1 - \theta L_y h)\|y' - y\|^2,
\]
so if $h < 1/(\theta L_y)$ we can take $\mu = (1 - \theta L_y h) > 0$. This (almost surely) guarantees the existence of a unique $Y_i(\omega) = F^{-1}(\mathbb{E}_i[(A_{i+1})(\omega)])$, as needed. By the monotonicity of $F$, $Y_i$ can be quickly computed using, for example, Newton-Raphson type methods. Now, $Y_i$ so defined is only an $\mathcal{F}_i$-measurable random variable.

The following proposition guarantees that if $\theta > 0$, the pair $(Y_i, Z_i)$ and the term $f_i$ are square integrable provided the corresponding random variables at $t_{i+1}$ also are. So for every $N$, by iteration, $(Y_i, Z_i)$ is well-defined for $i = N - 1, \cdots, 0$. For $\theta \geq 1/2$, this estimate also leads to a uniform bound, as will become clear in the next section (Proposition 5.1).

**Proposition 4.9.** Let (HX0), (HY0) hold, $\theta \in [0, 1]$ and take $h \leq \min\{1, [4\theta(L_y + 3d\theta L_z^2)]^{-1}\}$. Then there exists a constant $c$ such that for any $i \in \{0, \cdots, N - 1\}$
\[
|Y_i|^2 + \frac{1}{2d}Z_i|^2 h + 2\theta^2|f_i|^2 h^2 \leq (1 + ch)\mathbb{E}_i[|Y_{i+1}|^2] + \frac{1}{8d}|Z_{i+1}|^2 h + c(|X_i|^2 + \mathbb{E}_i[|X_{i+1}|^2])h + 2(1 - \theta)^2\mathbb{E}_i[|f_{i+1}|^2] h^2. \tag{4.18}
\]

**Proof of Proposition 4.9.** Let $i \in \{0, \cdots, N - 1\}$. First we estimate $Z_i$. The martingale property of $\Delta W_{i+1}$ yields
\[
Z_i h = \mathbb{E}_i[\Delta W_{i+1} A_{i+1}] = \mathbb{E}_i[\Delta W_{i+1} (A_{i+1} - \mathbb{E}_i[ A_{i+1}])]. \tag{4.19}
\]

By the Cauchy-Schwarz inequality,
\[
|Z_i|^2 h \leq d \{\mathbb{E}_i[A_{i+1}^2] - \mathbb{E}_i[A_{i+1}]^2\}. \tag{4.20}
\]

We now proceed with the estimation of $Y_i$. We first rewrite
\[
Y_i = \mathbb{E}_i[A_{i+1}] + \theta f_i h \iff Y_i - \theta f_i h = \mathbb{E}_i[A_{i+1}]
\]
and then square both sides of the RHS of the above equivalence to obtain
\[
|Y_i|^2 = \mathbb{E}_i[A_{i+1}]^2 + 2\theta(Y_i, f_i) h - \theta^2|f_i|^2 h^2.
\]
\[\]
This simple manipulation allows us to take advantage of the monotonicity of \( f \) (see (2.1)) and will be reused frequently. By the estimate of Remark 2.1, with an \( \alpha > 0 \) to be chosen later, the previous equality leads to

\[
|Y_i|^2 \leq \mathbb{E}_i[A_{i+1}]^2 + 2\theta(L_y + \alpha)|Y_i|^2 h + \theta B(i, \alpha) + \frac{3\theta L_2^2}{2\alpha} |Z_i|^2 h - \theta^2 |f_i|^2 h^2,
\]

where \( B(i, \alpha) := (3L_2^2 h + 3L_2^2 |X_i|^2 h)/(2\alpha) \). Now, for \( \epsilon = 1/d \), we combine the above estimate with (4.20) to obtain

\[
|Y_i|^2 + \epsilon |Z_i|^2 h \leq (1 - \epsilon d) \mathbb{E}_i[A_{i+1}]^2 + \epsilon d \mathbb{E}_i[A_{i+1}^2] + 2\theta(L_y + \alpha)|Y_i|^2 h + \frac{3\theta L_2^2}{2\alpha} |Z_i|^2 h + \theta B(i, \alpha) - \theta^2 |f_i|^2 h^2.
\]

Reorganizing the terms leads to

\[
\left(1 - 2\theta(L_y + \alpha) h\right)|Y_i|^2 + \left(\epsilon - \frac{3\theta L_2^2}{2\alpha}\right)|Z_i|^2 h \leq \mathbb{E}_i[A_{i+1}^2] + \theta B(i, \alpha) - \theta^2 |f_i|^2 h^2. \tag{4.21}
\]

Using again Remark 2.1 with \( \alpha' > 0 \) we obtain

\[
A_{i+1}^2 \leq |Y_{i+1}|^2 + (1 - \theta)2(L_y + \alpha')|Y_{i+1}|^2 h + (1 - \theta)\frac{3L_2^2}{2\alpha'} |Z_{i+1}|^2 h + (1 - \theta)B(i + 1, \alpha') + (1 - \theta)^2 |f_{i+1}|^2 h^2,
\]

which in turns leads to

\[
\left(1 - 2\theta(L_y + \alpha) h\right)|Y_i|^2 + \left(\epsilon - \frac{3\theta L_2^2}{2\alpha}\right)|Z_i|^2 h \leq \left(1 + (1 - \theta)2(L_y + \alpha') h\right) \mathbb{E}_i[|Y_{i+1}|^2] + (1 - \theta)\frac{3L_2^2}{2\alpha'} \mathbb{E}_i[|Z_{i+1}|^2] h + \theta B(i, \alpha) + (1 - \theta)\mathbb{E}_i[B(i + 1, \alpha')], \tag{4.22}
\]

where

\[
H_i^\theta := (1 - \theta)^2 \mathbb{E}_i[|f_{i+1}|^2] h^2 - \theta^2 |f_i|^2 h^2. \tag{4.23}
\]

Now, we choose \( \alpha = 3d\theta L_2^2 \) (so that \( \epsilon - \frac{3\theta L_2^2}{2\alpha} = \frac{1}{2d} \)) and \( \alpha' = 24d(1 - \theta) L_2^2 \) (so that \( (1 - \theta)\frac{3L_2^2}{2\alpha'} \leq \frac{1}{16d} \)). Since \( h \leq \min\{1, \frac{4\theta(L_y + 3d\theta L_2^2)}{1 - \theta}\} \) it is true that \( 2\theta(L_y + \alpha) h \leq 1/2 \). We also observe that for \( x \in [0,1/2], \ 1 \leq 1/(1 - x) \leq 1 + 2x \leq 2 \) and as a consequence

\[
|Y_i|^2 + \frac{1}{2d} |Z_i|^2 h \leq (1 + 4\theta(L_y + \alpha) h) (1 + 2(1 - \theta)(L_y + \alpha') h) \mathbb{E}_i[|Y_{i+1}|^2] + \frac{1}{8d} \mathbb{E}_i[|Z_{i+1}|^2] h + 2\theta B(i, \alpha) + 2(1 - \theta)\mathbb{E}_i[B(i + 1, \alpha')] + 2H_i^\theta.
\]

Defining \( c := 4\theta(L_y + \alpha) + 2(1 - \theta)(L_y + \alpha') + 8\theta(L_y + \alpha)(1 - \theta)(L_y + \alpha') \) we clearly have

\[(1 + 4\theta(L_y + \alpha) h)(1 + 2(1 - \theta)(L_y + \alpha') h) \leq 1 + ch.\]

We can now conclude to the announced estimate

\[
|Y_i|^2 + \frac{1}{2d} |Z_i|^2 h \leq (1 + ch) (\mathbb{E}_i[|Y_{i+1}|^2] + \frac{1}{8d} \mathbb{E}_i[|Z_{i+1}|^2] h) + 2\theta B(i, \alpha) + 2(1 - \theta)\mathbb{E}_i[B(i + 1, \alpha')] + 2H_i^\theta, \tag{4.24}
\]

provided one passes the term \(-2\theta^2 |f_i|^2 h^2 \) in \( 2H_i^\theta \) to the LHS. This concludes the proof. \( \square \)
4.6 Local time-discretization error

As announced in Subsections 4.2 and 4.3, we now proceed to estimating the one-step discretization errors $\tau_i(Y)$ and $\tau_i(Z)$ (see (4.9) for the definition), and then their sum. We thus obtain an estimate for the second group of terms in estimate (4.10), which is summarized in Proposition 4.13.

We follow the notation of Subsection 4.3 and write, for $i = 0, 1, \ldots, N-1$, $Y_i = Y_{i,(Y_{i+1},Z_{i+1})}$ and $\hat{Z}_i = Z_{i,(Y_{i+1},Z_{i+1})}$; that is $(\hat{Y}_i, \hat{Z}_i)$ is the solution to

$$
\hat{Y}_i = \mathbb{E}_t [Y_{i+1} + (1 - \theta) f(t_{i+1}, X_{i+1}, Y_{i+1}, \hat{Z}_{i+1}) h] + \theta f(t_i, X_i, \hat{Y}_i, \hat{Z}_i) h \tag{4.25}
$$

$$
\hat{Z}_i = \mathbb{E}_t \left[ \frac{\Delta W_{i+1}}{h} (Y_{i+1} + (1 - \theta) f(t_{i+1}, X_{i+1}, Y_{i+1}, \hat{Z}_{i+1}) h) \right]. \tag{4.26}
$$

Remark 4.10. We know from Proposition 4.9 that, for $h \leq \min \{1, [4\theta(L_y + 3d\theta L_y^2)]^{-1}\}$, the RV’s $(\hat{Y}_i, \hat{Z}_i)_{i=0,\ldots,N}$ are well defined and square integrable. Furthermore, estimate (4.18), together with the growth assumption on $f$ in (HY0), (4.1) for $X_{i+1}$, Theorem 2.2 for $Y_{i+1}$ and Corollary 3.6 for $\hat{Z}_{i+1}$, guarantee immediately that for any $p \geq 2$, there exists a constant $c$ such that

$$
\sup_{N \in \mathbb{N}} \max_{i=0,\ldots,N} \mathbb{E}[|\hat{Y}_i|^p] \leq c \tag{4.27}
$$

This fact will be needed later in Section 5 (in Lemma 5.3).

The next result estimates the one-step discretization errors $\tau_i(Y)$ and $\tau_i(Z)$ of the approximation in terms of the error process $R$ (as defined in (4.16)). Afterward we discuss the behavior of $R$ itself.

Lemma 4.11. Let (HX0) and (HY0) hold and assume that $h \leq 1/(4\theta L_y)$. Then for any $\theta \in [0,1]$ there exists a constant $c$ such that for any $i \in \{0, \ldots, N-1\}$

$$
\mathbb{E}[|Y_{i} - \hat{Y}_i|^2 + |Z_{i} - \hat{Z}_i|^2 h] \leq c \mathbb{E} \left[ \int_{t_i}^{t_{i+1}} R(s) \, ds \right]^2 + c L_y^2 \text{ERR}_R(X)^2 h^2.
$$

Proof. Let $i \in \{0, \ldots, N-1\}$. Recalling (4.15), (4.26) and that $\Theta_{i} := (X_{i}, Y_{i}, Z_{i})$ we have

$$
Z_{i} - \hat{Z}_i = \mathbb{E}_t \left[ \frac{\Delta W_{i+1}}{h} \left( (1 - \theta) [f(t_{i+1}, \Theta_{i+1}) - f(t_{i+1}, X_{i+1}, Y_{i+1}, \hat{Z}_{i+1})] h + \int_{t_i}^{t_{i+1}} R(s) \, ds \right) \right],
$$

which by the Cauchy-Schwartz’s inequality and the Lipschitz property of $x \mapsto f(\cdot,x,\cdot,\cdot)$ leads to

$$
h|Z_{i} - \hat{Z}_i|^2 \leq 2d \mathbb{E}_t \left[ \int_{t_i}^{t_{i+1}} R(\bar{u}) \, d\bar{u} \right]^2 + 2d(1 - \theta)^2 L_y^2 \mathbb{E}_t \left[ |X_{i+1} - X_{i+1}|^2 \right] h^2.
$$

For the $Y$-part, similarly by recalling (4.14) and (4.25) we have

$$
Y_{i} - \hat{Y}_i = \mathbb{E}_t \left[ \int_{t_i}^{t_{i+1}} R(s) \, ds + (1 - \theta) \left( f(t_{i+1}, \Theta_{i+1}) - f(t_{i+1}, X_{i+1}, Y_{i+1}, \hat{Z}_{i+1}) \right) h \right]
$$

$$
+ \theta \left( f(t_{i}, \Theta_{i}) - f(t_{i}, X_{i}, \hat{Y}_i, \hat{Z}_i) \right) h
$$

$$
= \mathbb{E}_t \left[ \int_{t_i}^{t_{i+1}} R(s) \, ds + (1 - \theta) \left( f(t_{i+1}, \Theta_{i+1}) - f(t_{i+1}, X_{i+1}, Y_{i+1}, \hat{Z}_{i+1}) \right) h \right]
$$

$$
+ \theta \left( f(t_{i}, X_{i}, Y_{i}, \hat{Z}_i) - f(t_{i}, X_{i}, \hat{Y}_i, \hat{Z}_i) \right) h
$$

$$
+ \theta \left( f(t_{i}, X_{i}, Y_{i}, \hat{Z}_i) - f(t_{i}, X_{i}, \hat{Y}_i, \hat{Z}_i) \right) h.
$$

28
To obtain the estimate for \(|Y_t - \hat{Y}_t|^2\), similarly as in the proof of Proposition 4.9, we pass the last term in the RHS to the LHS, square both sides, expand the square on the LHS, pass the cross term to the RHS and dominate it on the RHS using (2.1). By collecting only the convenient terms in the LHS and using Assumption (HY0) on the RHS we get

\[
|Y_t - \hat{Y}_t|^2 \leq 3 \mathbb{E}_t \left[ \int_{t_i}^{t_{i+1}} R(s) ds \right]^2 + 6 \theta^2 L_x^2 |\tilde{Z}_t - \hat{Z}_t|^2 h^2 + 2 \theta L_y |Y_t - \hat{Y}_t|^2 h
+ 6 \theta^2 L_x^2 |X_t - X_i|^2 h^2 + 3(1 - \theta)^2 L_x^2 \mathbb{E}_i[|X_{t_{i+1}} - X_{i+1}|^2] h^2,
\]

which implies, using the estimate for \(|\tilde{Z}_t - \hat{Z}_t|^2\), that

\[
(1 - 2\theta L_y h)|Y_t - \hat{Y}_t|^2 \leq (3 + 12 \theta^2 L_x^2 h) \mathbb{E}_t \left[ \left( \int_{t_i}^{t_{i+1}} R(s) ds \right)^2 \right] + 6 \theta^2 L_x^2 |X_t - X_i|^2 h^2
+ 3(1 - \theta)^2 L_x^2 (1 + 4 \theta^2 L_x^2 h) \mathbb{E}_i[|X_{t_{i+1}} - X_{i+1}|^2] h^2.
\]

Noting that \(h\) is such that \(2 \theta L_y h \leq 1/2\) and by combining the estimates for \(|Y_t - \hat{Y}_t|^2\) and \(|\tilde{Z}_t - \hat{Z}_t|^2\) the sought result follows after taking expectations and using (4.1) for \(X\).

We now estimate the integral of the error function \(R\) (see (4.16)).

**Lemma 4.12.** Let \((HX0), (HY0_{loc})\) hold. Then there exists \(c > 0\) such that, for any \(\theta \in [0, 1]\) and \(i \in \{0, \ldots, N - 1\}\),

\[
\mathbb{E} \left[ \left( \int_{t_i}^{t_{i+1}} R(s) ds \right)^2 \right] \leq c L_i^2 h^3 + c L_x^2 \text{REG}_\pi(X)^2 h^2 + c L_y \text{REG}_\pi(Y)^2 h^2
+ c L_x^2 \left[ \mathbb{E} \left[ \int_{t_i}^{t_{i+1}} |Z_s - \tilde{Z}_{t_i}|^2 ds \right] + \mathbb{E} \left[ \int_{t_i}^{t_{i+1}} |Z_s - \tilde{Z}_{t_{i+1}}|^2 ds \right] \right] h.
\]

**Proof.** Following from (4.16) we estimate \(R\) via \(R^l\) and \(R^E\) using \((HY0_{loc})\), Cauchy-Schwarz’s inequality and Fubini’s theorems we have (recall that \(\Theta = (X, Y, Z)\) and \(\Theta_t = (X_{t_i}, Y_{t_i}, \tilde{Z}_{t_i})\))

\[
\mathbb{E} \left[ \left( \int_{t_i}^{t_{i+1}} R^l(s) ds \right)^2 \right] = \mathbb{E} \left[ \left( \int_{t_i}^{t_{i+1}} [f(s, \Theta_s) \pm f(s, X_t, Y_t, Z_s) - f(t_i, \Theta_t)] ds \right)^2 \right]
\leq 2h \mathbb{E} \left[ \int_{t_i}^{t_{i+1}} 3L_y^2 (1 + |Y_s|^{2(m-1)} + |Y_{t_i}|^{2(m-1)}) |Y_s - Y_{t_i}|^2 ds + \alpha_t \right]
\leq 2h \left( \int_{t_i}^{t_{i+1}} L_y^2 \mathbb{E} \left[ 3(1 + |Y_s|^{4(m-1)} + |Y_{t_i}|^{4(m-1)}) \right]^{1/2} \mathbb{E} \left[ |Y_s - Y_{t_i}|^{4} \right]^{1/2} ds + \mathbb{E} [\alpha_t] \right),
\]

where \(\alpha_t = 3 \int_{t_i}^{t_{i+1}} \left[ L_i^2 |s - t_i| + L_x^2 |X_s - X_{t_i}|^2 + L_x^2 |Z_s - \tilde{Z}_{t_i}|^2 \right] ds\).

Using Theorem 2.2 to deal with the \(Y\) component, this yields the estimate

\[
\mathbb{E} \left[ \left( \int_{t_i}^{t_{i+1}} R^l(s) ds \right)^2 \right] \leq 3L_i^2 h^3 + 6L_y^2 \text{REG}_\pi(X)^2 h^2 + 18cL_y^2 \text{REG}_\pi(Y)^2 h^2
+ 6L_y^2 \mathbb{E} \left[ \int_{t_i}^{t_{i+1}} |Z_s - \tilde{Z}_{t_i}|^2 ds \right] h.
\]

Similar arguments allow a similar estimate for \(R^E\) but with terms \(t_{i+1}, X_{t_{i+1}}, Y_{t_{i+1}}\) and \(\tilde{Z}_{t_{i+1}}\) instead of \(t_i, X_{t_i}, Y_{t_i}\) and \(\tilde{Z}_{t_i}\). \(\square\)
The trapezoidal integration case

Here, we refine the analysis of the local discretization error from Lemma 4.12 for the case \( \theta = 1/2 \) in order to obtain better global error estimates. We drop the \( Z \)-dependence in \( f \) due to lacking regularity results. Approximation (4.5) is found by approximating the last integral on the RHS of (4.13) by a 1st order approximation and so, it should be clear that at best the overall order of the scheme would be one (in the next section we propose a candidate for higher order approximation of \( Z \)). We point out nonetheless that many reaction-diffusion equations have a driver \( f \) that only depends on \( Y \). For ease of the presentation we also assume that \( f \) does not depend on the forward process \( X \) and omit the time dependence (these can be easily extended).

We write, similarly to (4.14),

\[
\int_{t_i}^{t_{i+1}} f(Y_s) ds = \frac{h}{2} \left[ f(Y_{t_i}) + f(Y_{t_{i+1}}) \right] + \int_{t_i}^{t_{i+1}} R(s) ds, \quad R(s) := f(Y_s) - \frac{1}{2} \left[ f(Y_{t_i}) + f(Y_{t_{i+1}}) \right],
\]

where, using integration by parts, it can be shown (see [SM03]) that

\[
\mathbb{E} \left[ \left( \int_{t_i}^{t_{i+1}} R(s) ds \right)^2 \right] \leq \frac{h^6}{12^2} \mathbb{E} \left[ \sup_{t_i \leq t \leq t_{i+1}} \left| \partial^2_{yy} f(Y_t) \right|^2 \right]. \tag{4.28}
\]

Hence, in the special case where the driver of FBSDE under consideration does not depend on the process \((Z_t)_{0 \leq t \leq T}\) we can take full advantage of trapezoidal integration rule provided that the second derivatives of \( f \) in the \( y \) variable has polynomial growth, so that there exists a constant \( c \) for which

\[
\max_{t_i, t_{i+1} \in \pi} \mathbb{E} \left[ \sup_{t_i \leq t \leq t_{i+1}} \left| \partial^2_{yy} f(Y_t) \right|^2 \right] \leq c.
\]

The result on the sum of local errors

In view of the above lemmas (as well as the estimate (4.1) and the path-regularity Theorem 3.5), we can state the following estimates on the sum of the one-step discretization errors, as appearing in the global error estimate (4.10) of Lemma 4.6.

**Proposition 4.13.** Let \((HX0), (HY0_{loc})\) hold and \( h \leq \min\{1, [4\theta(L_y + 3d\theta L_y^2)]^{-1}\}\). For the scheme (4.4)-(4.5) we have the following local error estimates:

i) For any \( \theta \in [0, 1] \) \( \exists c > 0 \) such that \( \sum_{i=0}^{N-1} \frac{\tau_i(Y)}{h} \leq c h \) and \( \sum_{i=0}^{N-1} \tau_i(Z) \leq c h^2 \).

ii) Take \( \theta = 1/2 \) and scheme (4.4). Assume additionally that \( f \in C^2 \) does not depend on \((t, x, z)\) and \( \partial^2_{yy} f \) has at most polynomial growth, then there exists \( c > 0 \) such that \( \sum_{i=0}^{N-1} \frac{\tau_i(Y)}{h} \leq c h^4 \).

**Proof.** Recall the definition of \( \tau_i(Y) \) and \( \tau_i(Z) \) given in (4.9). The proof of case i) is simple: inject in the estimate of Lemma 4.11 that of Lemma 4.12 and then sum over \( i = 0 \) to \( i = N - 1 \). On the resulting inequality,

\[
\sum_{i=0}^{N-1} \tau_i(Y) + \tau_i(Z) \leq c L_y^2 h^2 + c L_y^4 \text{REG}_\pi(X)^2 h + c L_y^2 \text{REG}_\pi(Z)^2 h
\]

\[
+ c L_y^2 \text{REG}_\pi(Y)^2 h + c L_y^4 \text{ERR}_\pi(X)^2 h,
\]

apply (4.1) for \( \text{ERR}_\pi(X) \), the path-regularity result (4.2) for \( \text{REG}_\pi(X) \), and the path-regularity Theorem 3.5 for \( \text{REG}_\pi(Y) \) and \( \text{REG}_\pi(Z) \). Under \((HX0)\) and \((HY0_{loc})\) the resulting inequality is \( \sum_{i=0}^{N-1} (\tau_i(Y) + \tau_i(Z)) \leq c h^2 \). The statement’s inequalities now follows.

For the proof of case ii), remark that (4.25) is now independent of \( Z \), and hence using Lemma 4.11 in combination with (4.28) instead of Lemma 4.12 yields the result. \( \square \)
Remark 4.14. Under the assumption that $f$ only depends on $y$ (i.e., take $L_t = L_x = L_z = 0$) the methodology used above yields that the first terms in the global error $\text{ERR}_\pi(Y, Z)$ (see (4.10)) is controlled only by $\text{ERR}_\pi(X)$ and $\text{REG}_\pi(Y)$. The term $\text{REG}_\pi(Y)$ follows from the sum of the local discretization errors, as can be seen from above, while $\text{ERR}_\pi(X)$ follows from the approximation of the terminal condition.

These abstract estimates suggest that under stronger regularity assumptions on $f$ (stronger than $(HY_{0\infty})$), one may improve the estimates on $\tau(Y)$ and therefore obtain a higher convergence rate. Such developments are left for future research.

5 Convergence of the implicit-leaning schemes ($1/2 \leq \theta \leq 1$)

In this section, we complete the convergence proof of the theta scheme (4.4)-(4.5) for $\theta \in [1/2, 1]$ as stated in Theorem 4.2. In view of the Fundamental Lemma 4.6, Lemma 4.8 and Proposition 4.13, what remains to study is the stability of the scheme and estimate $R^S(H)$.

5.1 Integrability for the $\theta$-scheme, for $1/2 \leq \theta \leq 1$

We now show that for $\theta \geq 1/2$ the scheme cannot explode as $h$ vanishes. These $L^p$ estimates will be useful in obtaining the stability of the scheme.

Proposition 5.1. Let $(HX_0)$, $(HY_0)$ hold, and $h \leq \min\{1, [4\theta(L_y + 3d\theta L_z)]^{-1}\}$ and let $\theta \in [1/2, 1]$. Then for any $p \geq 1$, there exists a constant $c$ such that

$$\max_{i=0, \ldots, N} \mathbb{E}(|Y_i|^{2p}) + \sum_{i=0}^{N-1} \mathbb{E}(|Z_i|^{2p}) \leq c(1 + \mathbb{E}[|X_N|^{2mp}]).$$

Proof. Take $i \in \{0, \ldots, N - 1\}$. Let $I_i := |Y_i|^2 + \frac{1}{8d}|Z_i|^2h + \theta^2f(t_i, X_i, Y_i, Z_i)|2h^2$. By Proposition 4.9 and the fact that $(1 - \theta)^2 \leq \theta^2$, for $\theta \in [1/2, 1]$, we have

$$I_i + \frac{3}{8d}|Z_i|^2h \leq e^{c\mathbb{E}_t[I_{i+1}]} + \mathbb{E}_t[\beta_i]h, \quad \text{with} \quad \beta_i := c + c(|X_i|^2 + |X_{i+1}|^2). \quad (5.1)$$

As a consequence of Lemma A.4 we know that, since $\beta_j \geq 0$,

$$I_i + \frac{3}{8d}\mathbb{E}_t\left[\sum_{j=i}^{N-1} |Z_j|^2h\right] \leq e^{cT}\left(\mathbb{E}_t[I_N] + \sum_{j=i}^{N-1} \mathbb{E}_t[\beta_j]h\right).$$

in particular, using Jensen’s inequality, we obtain further

$$|I_i|^p \leq 2^{p-1}e^{cpT}\left(\mathbb{E}_t[|I_N|^p] + (Nh)^{p-1} \sum_{j=0}^{N-1} \mathbb{E}_t[|\beta_j|^p]h\right).$$

This then implies, thanks to $(HY_0)$

$$\max_{i=0, \ldots, N} \mathbb{E}[|I_i|^p] \leq c(1 + \mathbb{E}[|X_N|^{2mp}]) \implies \max_{i=0, \ldots, N} \mathbb{E}[|Y_i|^{2p}] \leq c(1 + \mathbb{E}[|X_N|^{2mp}]).$$

From (5.1) we also have

$$I_i^p + \left(\frac{3}{8d}\right)^p(|Z_i|^2h)^p \leq \left(I_i + \frac{3}{8d}|Z_i|^2h\right)^p \leq e^{cpT}\mathbb{E}_t[I_{i+1}^p] + \sum_{j=1}^{p} \left(\frac{p}{j}\right) \left(e^{c\mathbb{E}_t[I_{i+1}]}\right)^{p-j} \left(\mathbb{E}_t[\beta_i]h\right)^j.$$
so that, applying again Lemma A.4 along with Hölder’s and Jensen’s inequalities we have

\[
E \left[ \sum_{i=0}^{N-1} \left( |Z_i|^2 h \right)^p \right] 
\leq e^{c_p T} E[|I_N|^p] + \sum_{i=0}^{N-1} e^{c_i h} \sum_{j=1}^p \left( \frac{p}{j} \right) E \left[ e^{c_j \ell_i} \left( \mathbb{E}_{t_i} \left[ |I_{i+1}| \right] \right)^{p-j} \right] \left( \mathbb{E}_{t_i} [ |\tilde{\beta}| h ] \right)^j 
\leq e^{c_p T} E[|I_N|^p] + \frac{e^{c_p T}}{h} \sum_{i=0}^{N-1} \sum_{j=1}^p \left( \frac{p}{j} \right) \left( E[|I_{i+1}|^p] \right)^{\frac{p-j}{j}} \left( E[|\tilde{\beta}|^p] \right)^{\frac{j}{p}} \sum_{i=0}^{N-1} \sum_{j=1}^p \left( \frac{p}{j} \right) \left( E[|I_{i+1}|^p] \right)^{\frac{p-j}{j}} \left( E[|\tilde{\beta}|^p] \right)^{\frac{j}{p}}.
\]

Due to (HY0) and the previous estimates we arrive, as required, at

\[
E \left[ \sum_{i=0}^{N-1} \left( |Z_i|^2 h \right)^p \right] \leq c(1 + |X_N|^{2m_p}).
\]

\[\square\]

5.2 Stability of the \(\theta\)-scheme for \(1/2 \leq \theta \leq 1\)

We now study the stability of the scheme in the sense of (4.8). We fix \(i \in \{0, \ldots, N-1\}\) and estimate the distance between the outputs \((\hat{Y}_i, \hat{Z}_i)\) (see (4.25)-(4.26)) and \((Y_i, Z_i)\) (see (4.4)-(4.5)) as a function of the distance between the inputs \((Y_{i+1}, \hat{Z}_{i+1})\) and \((Y_{i+1}, Z_{i+1})\).

We use the notation \(\delta Y_{i+1} = Y_{i+1} - Y_{i}, \delta Z_{i+1} := Z_{i+1} - Z_i\), as well as
\[
\delta f_{i+1} = f(t_{i+1}, X_{i+1}, Y_{i+1}, \hat{Z}_{i+1}) - f(t_{i+1}, X_{i+1}, Y_{i+1}, Z_{i+1}) \quad \text{and} \quad \delta A_{i+1} = \delta Y_{i+1} + (1-\theta)\delta f_{i+1} h.
\]

Then, denoting by \(\hat{Y}_i = \hat{Y}_i - Y_i\), \(\hat{Z}_i = \hat{Z}_i - Z_i\), and \(\hat{f}_i = f(t_i, X_i, \hat{Y}_i, \hat{Z}_i) - f(t_i, X_i, Y_i, Z_i)\), we can write that (compare with (4.25), (4.26), (4.4) and (4.5))
\[
\hat{Y}_i = \mathbb{E}_i[\delta A_{i+1}] + \theta \delta f_{i+1} h \quad \text{and} \quad \hat{Z}_i = \mathbb{E}_i\left[ \frac{1}{h} \Delta W_{i+1} \delta A_{i+1} \right].
\]

**Proposition 5.2.** Let (HX0) and (HY0) hold. Then there exists a constant \(c\) for any \(i \in \{0, \ldots, N-1\}\) and \(h \leq \min\{1, 4\theta (L_y + d\theta L_Z^2)^{-1}\}\) such that
\[
|\hat{Y}_i|^2 + \frac{1}{2d} |\hat{Z}_i|^2 h \leq (1 + ch) \mathbb{E}_i[|\delta Y_{i+1}|^2 + \frac{1}{8d} |\delta Z_{i+1}|^2 h^2] + 2H_i^\theta,
\]
where
\[
H_i^\theta = (1 - \theta)^2 \mathbb{E}_i[|\delta f_{i+1}|^2] h^2 - \theta^2 \mathbb{E}_i[|\delta \hat{f}_i|^2] h^2. \quad (5.2)
\]

**Proof.** This proof is very similar to that of Proposition 4.9 therefore we omit it. \(\square\)

We want to control \(R^S(H)\). For the fully implicit scheme \((\theta = 1)\) we have \(H_i^\theta = -|\delta \hat{f}_i|^2 h^2 \leq 0\) and hence the implicit scheme is stable in the classical sense (of [Cha12] or [Cha13]) as we have \(R^S(H) \leq 0\). The next lemma provides, in our setting, a control on \(R^S(H)\) for any \(\theta \geq 1/2\).
Lemma 5.3. Let \((HX_0), (HY_0)\) hold and take the family \(\{H_i\}_{i=0, \ldots, N-1}\) defined in \(5.2\). Then for \(\theta \geq 1/2\) there exists a constant \(c\) such that

\[
\mathcal{R}^S(H) = \max_{i=0, \ldots, N-1} E \left[ \sum_{j=i}^{N-1} e^{c(j-i)\frac{1}{2}h} H_j \right] \leq c E[|Y_{iN} - Y_{iN}|^{4\frac{1}{2}h}] + c E[|\tilde{Z}_N - Z_N|^2] h^2
+ c \left( \sum_{i=0}^{N-1} \tau_i(Y) \right)^{\frac{1}{2}} h + c \left( \sum_{i=0}^{N-1} \tau_i(Z) \right)^{\frac{1}{2}} h.
\]

Proof. Let \(i \in \{0, \ldots, N-1\}\). Since \(1/2 \leq \theta \leq 1\), we have \((1-\theta)^2 \leq \theta^2\) and therefore

\[
E \left[ \sum_{j=i}^{N-1} e^{c(j-i)\frac{1}{2}h} H_j \right] \leq \theta^2 E \left[ \sum_{j=i}^{N-1} e^{c(j-i)\frac{1}{2}h} \left( |\delta f_{j+1}|^2 - |\delta \tilde{f}_j|^2 \right) h^2 \right]
= \theta^2 E \left[ \sum_{j=i}^{N-1} e^{c(j-i)\frac{1}{2}h} \left( |\delta f_{j+1}|^2 - |\delta f_j + \beta_j|^2 \right) h^2 \right]
\leq \theta^2 E \left[ \sum_{j=i}^{N-1} e^{c(j-i)\frac{1}{2}h} \left( |\delta f_{j+1}|^2 - |\delta f_j|^2 - 2 \langle \delta f_j, \beta_j \rangle - \beta_j^2 \right) h^2 \right]
\leq \theta^2 e^{c(N-i)\frac{1}{2}h} E[|\delta f_N|^2] h^2 - 2\theta^2 \sum_{j=i}^{N-1} e^{c(j-i)\frac{1}{2}h} \left( \langle \delta f_j, \beta_j \rangle \right) h^2,
\]

where \(\beta_j := \delta \tilde{f}_j - \delta f_j = f(t_i, X_j, \tilde{Y}_j, \tilde{Z}_j) - f(t_i, X_j, Y_i, \tilde{Z}_i)\) and we used a telescopic sum. Using now \((HY_0)_{loc}\) yields

\[
E[|\delta f_N|^2] \leq c E[1 + |Y_{iN}|^{4(m-1)} + |Y_N|^{4(m-1)}] \frac{1}{2} E[|Y_{iN} - Y_{iN}|^{\frac{1}{2}h}] + c E[|\tilde{Z}_N - Z_N|^2]
\]

and

\[
E[|\delta f_i, \beta_i|] h^2 \leq E[|\delta f_i|, |\beta_i|] h^2 \leq E\left[ \left( |\delta f_i|L_g(1 + |\tilde{Y}_i|^{m-1} + |Y_i|^{m-1}) \right)^{\frac{1}{2}} E[|\tilde{Y}_i - Y_i|] h^2 \right]
+ E\left[ (L_2|\delta f_i|)^{\frac{1}{2}} E[|\tilde{Z}_i - Z_i|^2] \right]^{\frac{1}{2}} h^2
\leq c E\left[ B_i^{\frac{1}{2}} \right]^{\frac{1}{2}} E[|\tilde{Y}_i - Y_i|^2]^{\frac{1}{2}} h + c E\left[ B_i^{\frac{1}{2}} \right]^{\frac{1}{2}} E[|\tilde{Z}_i - Z_i|^2 h]^2 h + 2E[|\tilde{Y}_i|^{4m} h^2 + |Y_i|^{4m} h^2 + (|\tilde{Z}_i|^2 h) h^2 + (|Z_i|^2 h)^2].
\]

From Theorem 2.2, Corollary 3.6, Remark 4.10 and Proposition 5.1 we have, for the first term of the above inequality

\[
\sum_{i=0}^{N-1} E\left[ B_i^{\frac{1}{2}} \right]^{\frac{1}{2}} E[|\tilde{Y}_i - Y_i|^2]^{\frac{1}{2}} h \leq \left( \sum_{i=0}^{N-1} E\left[ B_i^{\frac{1}{2}} \right] \right)^{\frac{1}{2}} \left( \sum_{i=0}^{N-1} \tau_i(Y) \right)^{\frac{1}{2}} h \leq c \left( \sum_{i=0}^{N-1} \tau_i(Y) \right)^{\frac{1}{2}} h
\]

and similarly for the second term

\[
\sum_{i=0}^{N-1} E\left[ B_i^{\frac{1}{2}} \right]^{\frac{1}{2}} E[|\tilde{Z}_i - Z_i|^2]^{\frac{1}{2}} h \leq c \left( \sum_{i=0}^{N-1} \tau_i(Z) \right)^{\frac{1}{2}} h.
\]
5.3 Convergence of the scheme

By collecting the above results we can now prove Theorem 4.2.

Proof of Theorem 4.2. The proof is a combination of the Fundamental Lemma 4.6, with Lemma 4.8, Proposition 4.13 and stability results obtained in this section, namely Proposition 5.2 and Lemma 5.3.

We move to the proof of part ii), the case \( \theta = 1/2 \). Since in this case \( f \) depends only on \( y \), a quick re-run of arguments of the Fundamental Lemma 4.6, shows there exists a constant \( c > 0 \) such that

\[
\max_{i=0,\ldots,N} \mathbb{E}[(Y_{t_i} - Y_{i+1})^2] \leq c\left\{ \mathbb{E}[|Y_{t_N} - Y_N|^2] + \sum_{i=0}^{N-1} \frac{\tau_i(Y)}{h} \right\} + (1 + h)\mathcal{R}^S(H).
\]

The first two terms on the RHS can be bounded by \( ch^{2\gamma} + ch^4 \), \( c > 0 \), using Lemma 4.8 and Proposition 4.13, respectively. By Lemma 5.3 there exists a constant \( c > 0 \) such that

\[
\mathcal{R}^S(H) \leq c\mathbb{E}[|Y_{t_N} - Y_N|^4]^{1/2}h^2 + c\left( \sum_{i=0}^{N-1} \tau_i(Y) \right)^{1/2}h,
\]

and using again Lemma 4.8 and Proposition 4.13 yields \( \mathcal{R}^S(H) \leq ch^{2\gamma + 2} + ch^{7/2} \). By joining these results the theorem’s conclusion follows.

5.4 Further remarks

Here, we discuss a true overall 2nd order scheme, namely a 2nd order discretization for \( Z \), and an intuitive variance reduction technique which we have used throughout but not made formally explicit.

5.4.1 The candidate for 2nd order scheme

For the general case where the driver depends on \( Z \), the approximation for \( Z_t \), namely (4.5), is not enough to obtain a higher order scheme as it is a 1st order approximation. The proper higher order scheme in its full generality follows by applying the trapezoidal rule to all integrals present in (4.13); as is done for (4.12). With some manipulation (left to the reader), we end up with the following approximation for \( Z_t \) (compare with (4.5)),

\[
Z_t = \frac{2}{h} \mathbb{E}_t[\Delta W_{t+1} \left( Y_{t+1} + (1 - \theta)f(t_i, X_{i+1}, Y_{i+1}, Z_{i+1})h \right)] - \mathbb{E}_t[Z_{i+1}],
\]

with \( \theta = 1/2 \), the terminal condition \( Y_N = g(X_N) \), along with (4.4) and a suitable approximation for \( Z_T \). An approximation for \( Z_T \) is not trivial and could, for instance, be found via Malliavin calculus. The general treatment of such a scheme is left for future research.

Another type of 2nd order scheme can be found in [CM10], the approximation there is based in Itô-Taylor expansions.

5.4.2 Controlling the variance of the scheme

If we use the notation set up in Subsection 4.5, the approximation (4.5) can be written out as \( Z_t = \mathbb{E}_t[\Delta W_{t+1} A_{i+1}] / h \). We point out that implementation wise it is better to use the lower variance
approximation (4.19) instead of (4.5), i.e. to use
\[
Z_i = \frac{1}{h} \mathbb{E}_i [\Delta W_{i+1} (A_{i+1} - \mathbb{E}_i [A_{i+1}])], \quad i = 0, \ldots, N - 1.
\]
This does not lead to a relevant additional computation effort, as \( \mathbb{E}_i [A_{i+1}] \) must be computed for the estimation of the \( Y_i \) component. To avoid a long analysis we make some simplifying assumptions
in order to better explain the gain: assume \( X_t = x + W_t \) and that we are about to compute \( Z_0 \) (a standard expectation); assume further (via Doob-Dynkin Lemma) that \( A_1 \) can be written as
\[
A_1 = \varphi(X_1) = \varphi(x + \Delta W_1) \text{ where } \varphi \text{ has some regularity so that}
\]
\[
\varphi(x + \Delta W_1) = \varphi(x) + \varphi'(x) (\Delta W_1) + \frac{1}{2} \varphi''(x^*) (\Delta W_1)^2,
\]
where \( x^* \) lies between \( x \) and \( x + \Delta W_1 \). Then the Monte-Carlo (MC) estimator for \( Z_0 \) from (4.5), with \( M \) samples of the normal \( \mathcal{N}(0, 1) \) distribution given by \{\( \mathcal{N}^\lambda \)\}_{\lambda=1,\ldots,M}, and its Standard deviation (Std) are
\[
Z_0^\text{MC,(4.5)} = \frac{1}{M} \sum_{\lambda=1}^{M} \frac{\sqrt{h} \mathcal{N}^\lambda}{h} \varphi(x + \sqrt{h} \mathcal{N}^\lambda) \quad \text{with} \quad \text{Std} \approx |\varphi(x)| \sqrt{\frac{h}{M}}.
\]
Using (4.19) instead of (4.5) to compute \( Z_0 \) would produce the MC estimator and its Std
\[
Z_0^\text{MC,(4.19)} = \frac{1}{M} \sum_{\lambda=1}^{M} \frac{\sqrt{h} \mathcal{N}^\lambda}{h} \left( \varphi(x + \sqrt{h} \mathcal{N}^\lambda) - \varphi(x) \right) \quad \text{with} \quad \text{Std} \approx |\varphi'(x)| \sqrt{\frac{1}{M}}.
\]
Compare now the standard deviation of both estimators. It is crucial for the stability that the denominator of the variance of \( Z_0^\text{MC,(4.19)} \) lacks that \( \sqrt{h} \) term. If \( M \) is kept fixed then as \( h \) gets smaller we expect \( Z_0^\text{MC,(4.5)} \) to blow up while \( Z_0^\text{MC,(4.19)} \) will remain controlled (assuming \( \varphi \) can be controlled\(^9\)). This can be numerically confirmed in [AA13].

We point out that this simple trick can be adapted to the scheme proposed in the next section as well as to the computation of the 2nd order scheme proposed previously.

6 Convergence of the tamed explicit scheme.

We now turn our attention back to the explicit scheme. Unlike the case \( \theta \in [1/2, 1] \), when \( \theta < 1/2 \), the local estimates of Proposition 4.9 cannot be extended to the global ones (as in Proposition 5.1).

Consequently, we also do not have a control over the stability remainder \( R^S(H) \) (see Definition 4.4). In fact, as the motivating example of the introduction shows, the scheme can explode. To remedy to this, we consider the tamed explicit scheme, described in (4.6)-(4.7), which in turn corresponds to a truncation procedure applied to the original BSDE, and show that this scheme converges. Our analysis yields as a by-product sufficient conditions under which the naive explicit scheme converges (see Remark 6.6).

Remark 6.1 \((m > 1)\). In this section we focus exclusively on the case \( m > 1 \) in Assumptions \( (HY0) \). The easier case \( m = 1 \) does not require taming and stability of the scheme results from a straightforward adaptation of the proof of Proposition 6.4.

\(^9\)If the reader is aware of how conditional expectations in the BSDE framework are calculated, say e.g. via projection over a basis of functions, having a function \( \varphi \) is expected.

\(^{10}\)In [GT14] it is shown for the locally Lipschitz driver case that \( \varphi \) is indeed a Lipschitz function of its variables.
6.1 Principle

The idea is that with the truncation functions $T_{L_h}$ and $T_{K_h}$ (recall the scheme (4.6)-(4.7)), one can not only obtain uniform integrability bounds for the scheme, but also a pathwise bound, ensuring that the output $\{Y_t\}_{t=0,...,N}$ stays under a certain threshold, under which the scheme is found to be stable in the sense of (4.8) with $H_t = 0$.

Note that this tamed scheme is not exactly the scheme (4.4)-(4.5) with $\theta = 0$. However it can be seen as the case $\theta = 0$ with the functions $T_{L_h} \circ g$ and $f(\cdot, T_{K_h}(\cdot), \cdot)$ instead of $g$ and $f$. They satisfy the same properties with the same constants, so we can reuse the results of Section 4.

Because the scheme is controlled, we naturally compare first its output $\{(Y_t, Z_t)\}_{t\in[0,...,N]}$ to $(Y'_t, Z'_t)_{t\in\pi}$, where $(Y'_t, Z'_t)_{t\in[0,T]}$ is the solution to the BSDE (1.2) with controlled coefficients:

$$Y'_t = T_{L_h}(g(X_T)) + \int_t^T f(u, T_{K_h}(X_u), Y'_u, Z'_u)du - \int_t^T Z'_udW_u, \quad t \in [0, T]. \quad (6.1)$$

This part of analysis follows the methodology used above.

In a second step, it is enough to estimate the distance between the solution $(Y', Z')$ of the truncated BSDE (6.1) and the solution $(Y, Z)$ of the original BSDE (1.2) in order to conclude to the convergence of the scheme.

In line with Section 4 and 5 we define $\{\hat{Z}'_t\}_{t\in\pi}$ as in (3.23), $\hat{Y}_t = Y_t(Y'_{t+1}, \hat{Z}'_{t+1})$ and $\hat{Z}_t = Z_t(Y'_{t+1}, \hat{Z}'_{t+1})$ for $i = 0, \ldots, N - 1$, more precisely

$$\hat{Y}_i := E_t \left[ Y_{t+1} + f(t_{i+1}, T_{K_h}(X_{i+1}), Y'_{t+1}, \hat{Z}'_{t+1})h \right], \quad (6.2)$$

$$\hat{Z}_i := E_t \left[ \frac{\Delta W_{i+1}}{h} \left( Y'_{t+1} + f_h(t_{i+1}, X_{i+1}, Y'_{t+1}, \hat{Z}'_{t+1})h \right) \right]. \quad (6.3)$$

6.2 Integrability for the scheme

We now show that the tamed Euler scheme has the property that $|Y_i| \leq h^{-1/(2m-2)}$ for all $i \in \{0, \ldots, N\}$. This is already true for $Y_N = T_{L_h}(g(X_N))$ by construction. In the next two propositions we will show that this bound propagates through time.

**Proposition 6.2.** Assume (HX0), (HY0) and that $h \leq 1/(32dL^2_x)$. If for a given $i \in \{0, \ldots, N-1\}$ one has $|Y_{i+1}| \leq h^{-1/(2m-2)}$, then one also has

$$|Y_i|^2 + \frac{1}{d} |Z_i|^2 h \leq (1 + c_1 h) E_t \left[ |Y_{i+1}|^2 + \frac{1}{4d} |Z_{i+1}|^2 h \right] + c_2 h + c_2 h E_t \left[ |T_{K_h}(X_{i+1})|^2 \right].$$

**Proof.** Take $i \in \{0, \ldots, N-1\}$. We have seen in the proof of Proposition 4.9, equation (4.22) that, since $\theta = 0$,

$$|Y_i|^2 + \frac{1}{d} |Z_i|^2 h \leq \left( 1 + 2(L_y + \alpha') \right) E_t \left[ |Y_{i+1}|^2 + \frac{3L^2}{2\alpha'} E_t \left[ |Z_{i+1}|^2 \right] h + E_t[B(i+1, \alpha')] + H^0_i \right],$$

where $B(i+1, \alpha') := (3L^2 h + 3L^2_x |T_{K_h}(X_{i+1})|^2 h^2)/2\alpha'$ and

$$H^0_i = E_t \left[ |f_{i+1}|^2 \right] h^2 = E_t \left[ |f(t_{i+1}, T_{K_h}(X_{i+1}), Y_{i+1}, Z_{i+1})|^2 \right] h^2.$$

Using (HY0) and the fact that $|Y_{i+1}|^{2(m-1)} h \leq 1$, we have

$$|f_{i+1}|^2 h^2 \leq 4L^2 h^2 + 4L^2_x |T_{K_h}(X_{i+1})|^2 h^2 + 4L^2_y |Y_{i+1}|^2 (m-1) h) |Y_{i+1}|^2 h^2 + 4L^2_x |Z_{i+1}|^2 h^2$$

$$\leq 4L^2 h^2 + 4L^2_x |T_{K_h}(X_{i+1})|^2 h^2 + 4L^2_y |Y_{i+1}|^2 h + 4L^2_x |Z_{i+1}|^2 h,$$
so we have in the end
\[
|Y_i|^2 + \frac{1}{d} |Z_i|^2 h \leq \left( 1 + 2(L_y + \alpha' + 2L_y^2)h \right) \mathbb{E}_t \left[ |Y_{i+1}|^2 \right] + \left( \frac{3L^2}{2\alpha'} + 4L^2 h \right) \mathbb{E}_t \left[ |Z_{i+1}|^2 \right] h \\
+ \left( \frac{3L^2}{2\alpha'} + 4L^2 h \right) h + \left( \frac{3L^2}{2\alpha'} + 4L^2 h \right) \mathbb{E}_t \left[ |T_{K_h}(X_{i+1})|^2 \right] h.
\]
Choose now $\alpha' = 12dL_z^2$ (so that $3L_z^2/(2\alpha') \leq 1/(8d)$) and combine with the restriction $h \leq 1/(32dL_z^2)$ (so that $4L_z^2 h \leq 1/8d$). Taking $c_1 = 2(L_y + 12dL_z^2 + 2L_y^2)$ and
\[
c_2 = \max \left\{ \frac{3L^2}{24dL_z^2}, \frac{4L^2}{32dL_z^2}, \frac{3L^2}{24dL_z^2}, \frac{4L^2}{32dL_z^2} \right\} = \max \left\{ \frac{L^2}{4dL_z^2}, \frac{L^2}{4dL_z^2} \right\},
\]
and noting that $1/(4d) \leq (1 + c_1 h)/(4d)$, we find the required estimate
\[
|Y_i|^2 + \frac{1}{d} |Z_i|^2 h \leq (1 + c_1 h) \mathbb{E}_t \left[ |Y_{i+1}|^2 + \frac{1}{4d} |Z_{i+1}|^2 h \right] + c_2 h + c_2 h \mathbb{E}_t \left[ |T_{K_h}(X_{i+1})|^2 \right].
\]

We can then use this local bound to obtain the following pathwise bound.

**Proposition 6.3.** Let (Hx0) and (Hy0) hold. For any $i \in \{0, \ldots, N-1\}$,
\[
|Y_i|^2 + \frac{1}{d} |Z_i|^2 h + \frac{3}{4d} \mathbb{E}_t \left[ \sum_{j=1}^{N-1} |Z_j|^2 h \right] \\
\leq e^{c_1(N-i)h} \mathbb{E}_t \left[ |Y_N|^2 \right] + e^{c_1(N-1-i)h} \left( \sum_{j=i}^{N-1} c_2 h + c_2 h \mathbb{E}_t \left[ |T_{K_h}(X_{i+1})|^2 \right] \right).
\]
This implies in particular that $|Y_i| \leq h^{-1/(2m-2)}$.

**Proof.** The proof goes by induction. The case $i = N$ is clear. If the estimate is true for $i + 1$, noting that $|Y_N| \leq L_h$, $|T_{K_h}(x)| \leq K_h$ and $e^{c_1 T} \left( L_h^2 + c_2 T + c_2 T K_h^2 \right) \leq h^{-1/(m-1)}$, we see that $|Y_{i+1}|^2 \leq h^{-1/(m-1)}$. Then, combining the estimate of Proposition 6.2 and the estimate for $i + 1$ (from the induction assumption), in the same way as in Lemma A.4, we obtain the desired estimate for $i$.

In view of the previous bound, we can derive a similar estimate for the solution $(Y', Z')$ to (6.1). Namely, using (2.5) with $\alpha = 12dL_z^2$ and combining it further with (Hy0), we have
\[
|Y'_i|^2 \leq e^{2(L_y + 12dL_z^2)(T-t)} \mathbb{E}_t \left[ |T_{L_h}(g(X_T)|^2 + \int_t^T \frac{1}{16dL_z^2} |f(u, T_{K_h}(X_u), 0, 0)|^2 du \\
\leq e^{c_1(T-t)} \mathbb{E}_t \left[ |T_{L_h}(g(X_T)|^2 + \int_t^T \frac{1}{8dL_z^2} (L^2 + L_z^2 |T_{K_h}(X_u)|^2) du \\
\leq e^{c_1 T} \left( L_h^2 + c_2 T + c_2 T K_h^2 \right) \leq \left( \frac{1}{h} \right)^{\frac{1}{m-1}},
\]
implying in particular that $|Y'_i| \leq h^{-1/(2m-2)}$ for all $i$.

These two estimates, ensuring that both $Y_i$ and $Y'_i$ are bounded by $h^{-1/(2m-2)}$ will be useful in the analysis of the global error, since the explicit scheme is found to be stable under this threshold.
6.3 Stability of the scheme.

As previously, for any $i \in \{0, \ldots, N - 1\}$ we use the notation $\delta Y_{i+1} := Y_{i+1} - Y_i$ and $\delta Z_{i+1} := Z_{i+1} - Z_i$, as well as $\delta A_{i+1} := \delta Y_{i+1} + \delta f_{i+1}$ where $\delta f_{i+1}$ is given by

$$
\delta f_{i+1} := f(t_{i+1}, T_{K_h}(X_{i+1}), Y'_{i+1}, Z'_{i+1}) - f(t_{i+1}, T_{K_h}(X_{i+1}), Y_{i+1}, Z_{i+1}).
$$

Then, denoting $\delta Y_i = \hat{Y}_i - Y_i$ and $\delta Z_i = \hat{Z}_i - Z_i$, we can write

$$
\delta Y_i = \mathbb{E}_i[\delta A_{i+1}] \quad \text{and} \quad \delta Z_i = \mathbb{E}_i\left[\frac{1}{h} \Delta W_{i+1} \delta A_{i+1}\right].
$$

We now proceed to show that, because the two inputs satisfy $|Y_{i+1}|, |Y'_{i+1}| \leq h^{-1/(2m-2)}$, the scheme is stable in the sense that we can obtain the estimate (4.8) with $H_i = 0$.

**Proposition 6.4.** Assume (HX0) and (HY0$\text{loc}$). Then there exists a constant $c$ for any $h \leq \min\{1, 1/32dL_2^2\}$, such that

$$
|\delta Y_i|^2 + \frac{1}{d} |\delta Z_i|^2 h \leq (1 + ch) \mathbb{E}_i[|\delta Y_{i+1}|^2 + \frac{1}{4d} |\delta Z_{i+1}|^2 h], \quad i \in \{0, \ldots, N - 1\}.
$$

**Proof.** Let $i \in \{0, \ldots, N - 1\}$. Just like for Proposition 5.2, the proof mimics the computations of the proof of Proposition 4.9 with only a small adjustment for the constants. However, a different argument for the term $H_i^0 = |\delta f_{i+1}|^2 h^2$ is required. Using (HY0$\text{loc}$), $h \leq 1$ and the bounds $|Y_{i+1}|^2 h^2, |Y'_{i+1}|^2 h^2 \leq 1$, we have

$$
|\delta f_{i+1}|^2 h^2 \leq 2L_y^2 (1 + |Y'_{i+1}|^2 h^2 + |Y'_{i+1}|^2 h^2) Y_{i+1}^2 - Y_i^2 h^2 + 2L_z^2 |Z_{i+1}^2 - Z_i^2 h^2
= 2L_y^2 (h + |Y'_{i+1}|^2 h + |Y'_{i+1}|^2 h) Y_{i+1}^2 - Y_i^2 h^2 + 2L_z^2 |Z_{i+1}^2 - Z_i^2 h^2
\leq 6L_y^2 |\delta Y_{i+1}|^2 + 2L_z^2 h |\delta Z_{i+1}|^2 h.
$$

The rest follows as in the proof of Proposition 4.9. \qed

6.4 Convergence of the scheme

The convergence of the scheme is achieved by controlling both the (squared) error committed by the truncation procedure, $\|Y - Y'\|^2_{L_2} + \|Z - Z'\|^2_{L_2}$, as a function of the time step, and by controlling the numerical approximation (4.6)-(4.7) of the solution $(Y', Z')$ to (6.1).

**Distance between $(Y_i, Z_i)$ and $(Y'_{i+1}, Z'_{i+1})$**

We estimate this distance by using the Fundamental Lemma 4.6.

The tamed scheme (4.6)-(4.7) is the $\theta = 0$ scheme (4.4)-(4.5) with the coefficient $f(\cdot, \cdot, T_{K_h}(\cdot), \cdot)$ and terminal condition $T_{K_h} \circ g$ having the same Lipschitz constant as $f$ and $g$. So the results of Section 4 apply. In particular, Lemma 4.8 controls the error on the terminal condition.

Similarly, Lemma 4.11 and Lemma 4.12 are still valid with the same constants. The only difference is that the path-regularity involved is now that of $(Y', Z')$, but since $T_{K_h} \circ g$ is still Lipschitz, Theorem 3.5 indeed applies to $(Y', Z')$. So Proposition 4.13 applies, to control the sum of the one-step discretization errors.
Finally, we have just proven with Proposition 6.4 that the scheme is stable with $H^0_t = 0$, so $\mathcal{R}^S(H) = 0$. We can therefore conclude via Lemma 4.6 that

$$\max_{i=0,\ldots,N} \mathbb{E}[|Y^i_t - Y^i_i|^2] + \sum_{i=0}^{N-1} \mathbb{E}[|Z^i_t - Z^i_i|^2]h$$

$$\leq c \left( \mathbb{E}[|Y^i_N - Y_N|^2] + \mathbb{E}[|Z^i_N - Z_N|^2]h \right) + c \sum_{i=0}^{N-1} \left( \frac{1}{h} \tau_i(Y) + \tau_i(Z) \right) + 0 \leq ch.$$

We remark that the thresholds $L_h$ and $K_h$ have no effect in this estimation.

The Distance between $(Y^i_t, Z^i_t)$ and $(Y^j_t, Z^j_t)$

We now estimate the distance between $(Y^i_t, Z^i_t)$ and $(Y^j_t, Z^j_t)$, i.e. between (6.1) and (1.2), which gathers all the error induced by the taming. In order to estimate this error, we need to have an estimation of the $L^2$-distance between $X_u$ and $T_{K_h}(X_u)$ on the one hand, and $g(X_T)$ and $T_{L_h}(g(X_T))$ on the other. We give a general estimation for this below.

**Proposition 6.5.** Let $\xi$ be a random variable in $L^q$ for some $q > 2$, and $L > 0$. Then we have

$$\mathbb{E}[|\xi - T_L(\xi)|^2] \leq 4\mathbb{E}[|\xi|^q] \left( \frac{1}{L} \right)^{q-2}.$$

**Proof.** Using the facts that $T_L(x) = x$ for $|x| \leq L$ and that $|T_L(\xi)| \leq |\xi|$, together with the Hölder and the Markov inequalities, we have

$$\mathbb{E}[|\xi - T_L(\xi)|^2] = \mathbb{E}[|\xi - T_L(\xi)|^2 \mathbb{1}_{\{\xi \geq L\}}] \leq 4\mathbb{E}[|\xi|^q \mathbb{1}_{\{\xi \geq L\}}]$$

$$\leq 4\mathbb{E}[|\xi|^q \mathbb{1}_{\{\xi \geq L\}}] \leq 4\mathbb{E}[|\xi|^q] \left( \frac{\mathbb{E}[|\xi|^q]}{L^q} \right)^{1-\frac{2}{q}} = 4\mathbb{E}[|\xi|^q] \left( \frac{1}{L} \right)^{q-2}.$$

Now, via Jensen’s inequality we have

$$|Z_{t_i} - Z'_{t_i}|^2h = \left| \frac{1}{h} \mathbb{E}_t \left[ \int_{t_i}^{t_{i+1}} Z_u du \right] - \frac{1}{h} \mathbb{E}_t \left[ \int_{t_i}^{t_{i+1}} Z'_u du \right] \right|^2h \leq \mathbb{E}_t \left[ \int_{t_i}^{t_{i+1}} |Z_u - Z'_u|^2 du \right],$$

from which it clearly follows that

$$\max_{i=0,\ldots,N} \mathbb{E}[|Y^i_t - Y^i_i|^2] + \sum_{i=0}^{N-1} \mathbb{E}[|Z^i_t - Z^i_i|^2]h \leq \sup_{t \in [0,T]} \mathbb{E} \left[ |Y_t - Y_t'|^2 \right] + \mathbb{E} \left[ \int_0^T |Z_u - Z'_u|^2 du \right].$$

From the a priori estimate (2.6) we have

$$\sup_{t \in [0,T]} \mathbb{E}[|Y_t - Y'_t|^2] + \mathbb{E} \left[ \int_0^T |Z_u - Z'_u|^2 du \right]$$

$$\leq c \left( \mathbb{E}[|g(X_T) - T_{L_h}(g(X_T))|^2] + \mathbb{E} \left[ \int_0^T |f(u, X_u, Y'_u, Z'_u) - f(u, T_{K_h}(X_u), Y'_u, Z'_u)|^2 du \right] \right)$$

$$\leq c \left( \mathbb{E}[|g(X_T) - T_{L_h}(g(X_T))|^2] + L^2 \int_0^T \mathbb{E}[|X_u - T_{K_h}(X_u)|^2] du \right)$$

$$\leq c \left( 4 \left( \frac{1}{L_h} \right)^{2m-2} \mathbb{E}[|g(X_T)|^{2m}] + \left( \frac{1}{K_h} \right)^{2m-2} 4L^2 \int_0^T \mathbb{E}[|X_u|^{2m}] du \right),$$

39
thanks to Proposition 6.5. Now, since $X \in \mathcal{S}^{2m}$ (Theorem 2.2), $g$ is of linear growth, and $L_h$ and $K_h$ are of order $h^{-1/(2m-2)}$, we can conclude that

$$
\max_{i=0,\ldots,N} \mathbb{E}[|Y_{ti} - Y'_{ti}|^2] + \sum_{i=0}^{N-1} \mathbb{E}[|\bar{Z}_{ti} - \bar{Z}'_{ti}|^2]h \leq ch.
$$

(6.5)

The proof of the Theorem 4.3

By collecting the above results we can now prove Theorem 4.3.

Proof of Theorem 4.3. To prove this theorem, i.e. that $\text{ERR}_\pi(Y, Z) \leq ch^{1/2}$ (see (4.3)), we use the triangular inequality and dominate $\text{ERR}_\pi(Y, Z)$ by the sum of: i) the distance between the solution $(Y, Z)$ to the original BSDE (1.2) and the solution $(Y', Z')$ to the truncated BSDE (6.1), and ii) the distance between $(Y'_{ti}, \bar{Z}'_{ti})_{t_i \in \pi}$ and the $\{(Y_i, Z_i)_{t_i \in \pi}\}$ (from the scheme (4.6)-(4.7)). Hence the result.

Remark 6.6. We see from the proofs of Propositions 6.2 and 6.3 that if $x \mapsto f(t, x, y, z)$ is bounded (say, by $K$) uniformly in the other variables and the terminal condition $g$ is bounded, then the naive explicit scheme (i.e. (4.4)-(4.5) with $\theta = 0$) converges. Under these conditions, it is suitable to use the explicit backward Euler scheme.

7 Numerical experiments

We conclude with some numerical experiments for the convergence of the introduced schemes. In this work, we are concerned only with the time-discretization, but in order to implement a scheme, we need to further approximate the required conditional expectations. For this, we use the method of regression on a basis functions as in [GLW05], [GT14]. Following [GLW05] we work with (Hermite) polynomials up to a certain degree $K$. Here, we do not aim at studying the effect of the number $K$ of basis functions or the number $M$ of diffusion paths $\{X^m_{t_i}\}_{t_i \in \pi}$. Rather, we choose $K$ and $M$ big enough so that a) the variance of the results is small enough, and b) the effect of approximating the conditional expectation is negligible and so what we measure is indeed the effect on the time-discretization of the time-step $h = T/N$.

In all the examples below, we fix terminal time $T$ and want to compute an approximation of $u(t, X_t) = Y_t =: Y^\text{true}$. Since in this section we use grids with different numbers $N$ of intervals, we do not omit the superscripts and denote by $Y^N_i$ the scheme’s approximation of $Y^\text{true}_i$. When the explicit solution to the FBSDE is known, we can measure the error of the numerical approximation by estimating $\text{ERR}(Y^N) = \max_i \mathbb{E}[|Y^\text{true}_i - Y^N_i|^2]^{1/2}$. When the explicit solution is not known, we can compute

$$
e(N) := \max_{i=0,\ldots,N} \mathbb{E}\left[|Y^N_i - Y^\text{true}_i|^2\right]^{1/2}.
$$

(7.1)

By observing the convergence of $\ne(N)$ we can measure the convergence rate of the scheme even when we do not know the true solution. Indeed, assume that for constants $c$ and $\gamma$, for any $N$ and any $i = 0, \ldots, N$ we have

$$
\mathbb{E}\left[|Y^N_i - Y^\text{true}_i|^2\right]^{1/2} \leq cN^{-\gamma}, \quad \text{then}\quad \mathbb{E}\left[|Y^N_i - Y^\text{true}_i|^2\right]^{1/2} \leq \sum_{k=0}^{\infty} c(2^kN)^{-\gamma} = \frac{cN^{-\gamma}}{1 - (1/2)^\gamma} = c'N^{-\gamma},
$$

40
given that the scheme converges.

We computed the approximation processes \((Y^N)\) and \((Y^{2N})\) using the same sample of Brownian increments. For each measurement, we launched the scheme 10 times and averaged the results.

**Example 1 - numerical approximation for Example 2.8**

We consider the motivating FitzHugh-Nagumo PDE and the terminal condition \(g\) of Example 2.8 with \(a = -1\), for which \(f(t, x, y, z) = -y^3 + y\): a cubic polynomial (without quadratic terms).

To solve the implicit equation (see (4.4)) we can use Cardano’s formula to compute the single real root of the polynomial equation.

We take \(T = 1\) and \(x_0 = 3/2\). The solution to the PDE is given by (2.11). We compute the error for various values of \(N\), and this for the explicit scheme \((\theta = 0\), which converges in that case since \(g\) is bounded —see Remark 6.6), the implicit scheme \((\theta = 1)\) and the trapezoidal scheme \((\theta = 1/2)\), note that we are under the extra assumptions made in Theorem 4.2-

![Graph](image)

**Figure 1:** (a) Differences \(Y^N_0 - Y^{true}_0\) for each scheme as functions on the number \(N\) of time intervals. (b) Convergence rates obtained via linear fits on the log-log plots of \(ERR(Y^N)\). We used \(N \in \{10, 20, 30, 40, 50, 60, 70\}\), Hermite polynomials up to degree \(K = 7\), \(M = 2 \times 10^5\) and 10 simulations for each point.

**Table 1:** Estimated rates (value of slope) for the experiment reported in Figure 1.

In Figure 1(a) we see that the implicit scheme overshoots the true solution while the explicit one undershoots it; the trapezoidal scheme performs better in any grid. The convergence rates, as measured using \(ERR(Y^N)\), are presented in Figure 1(b). For the trapezoidal scheme, the error for any \(N\) is very small and the variance of the results is not negligible, hence we are not able to measure
the convergence rate as accurately. The experimental rate seems to be lower than that of the explicit and implicit. We note however that the error is already much lower than those in the other schemes.

Both the implicit and explicit schemes are found to converge with rate 1. This does not mean that the estimates in Theorems 4.2 and 4.3 (or that in the Fundamental Lemma 4.6) are too conservative in all generality, but is simply due to the particularity of the equation studied. On the one hand, the estimates of Theorems 4.2 and 4.3 rely on the estimate of Proposition 4.11 (on the local discretization errors) and so on the regularity of $b, \sigma, f$ and $g$. We worked under the minimal assumption (HY0$_{\infty}$) assuming no differentiability. Nonetheless, in this example all involved functions are smooth (leading to a smooth solution $u$ to the PDE) and so this term ends up converging faster (see also Remark 4.14). On the other hand, the estimates of Theorems 4.2 and 4.3 also rely on the estimate of Lemma 4.8 (on the terminal condition error) which again holds under the mere assumption (HX0) for $b$ and $\sigma$. But here $(X_t)$ is the Brownian motion and its approximation $(X^N_t)$ is exact, instead of being only of order $\gamma = 1/2$ in the case of Euler-Maruyama scheme.

As we could verify in our simulations, the computational time is the same for all the schemes with $\theta > 0$, as expected. On the other hand, similarly to the case of ODEs and SDEs, the convergence rate for $\theta \in [1/2, 1]$ is no better than for $\theta = 1$. However, the latter choice is more stable (compare with the definition of $R^{\theta}(H)$ and $H^{\theta}$) while $\theta = 1/2$ provides the smallest error. A more detailed comparison between the different implicit-dominating schemes is left to a forthcoming work.

Finally, while we were able to compute $ERR(Y^N)$ in this example, we also computed $e(N)$. Since we approximated the solution using polynomials up to degree $K$, the full (implemented) scheme computes in fact an approximated process $Y^{N,K}$. As $N \to +\infty$, this does not strictly converge to $Y^{true}$ but rather to some $Y^K$. The convergence of $e(N)$ therefore better captures the convergence of $Y^{N,K}$ to its limit, $Y^K$, and therefore yields slightly different rates.

Example 2 - unbounded terminal condition

To emphasize the contribution of this work we analyze in more detail the unbounded terminal condition case for which one needs to take either the implicit scheme or the explicit scheme with truncated terminal condition. More precisely, we take $g(x) = x$, together with the driver $f(y) = -y^3$. For the forward process we take the geometric Brownian motion with $b(x) = x/2$ and $\sigma(x) = x/2$, started at $x_0 = 2$. We choose $T = 1$.

Figure 2(a) shows the convergence of $e(N)$ (see (7.1)) for the implicit scheme, while Figure 2(b) shows the same computations for the truncated explicit scheme. The implicit scheme converges with the rate 1/2, as expected. Concerning the truncated explicit scheme (Figure 2(b)) we observed through several trials that its behavior is quite sensitive to the truncation level $L_h$ (defined in subsection 4.2.2)\(^{11}\). Our asymptotic, theoretical results (see (4.6), (4.7) and Theorem 4.3) suggest to take for this particular example $L_h$ as

$$L_h = \frac{1}{\sqrt{3}} e^{-\frac{3}{2} T} \left(\frac{1}{h}\right)^{\frac{1}{2}}.$$

We found however that this seems to be too conservative for practical simulations. To better understand the impact of truncation, we introduced a multiplying factor $\alpha > 0$ and truncate at the level $\alpha L_h$ instead of $L_h$. In Figure 2(b) and Table 2 we sum up our findings. In Table 2 one sees the various multiplying factors and the corresponding estimated rates (for the sequence $e(N)$ defined in (7.1)).

\(^{11}\)This echoes the findings of [CR13].
Figure 2: (a) Convergence of $e(N)$ for the implicit scheme (b) Convergence of $e(N)$ for the tamed explicit scheme and various values of the multiplying factor. In both cases we used $N \in \{5i : i = 7, \cdots, 18\}$, $K = 4$, $M = 10^5$, and 10 simulations for each point. The results are plotted in log-log scale.

Table 2: Estimated rate for the truncated explicit scheme at truncation level $\alpha L_h$.

By looking at Figure 2(b) we see that the situation is complex and a separate argumentation is required for “small” and “big” multiplying factors. For $\alpha$ too small (up to 40) the scheme does not seem to converge. This is due to the fact that a significant number of forward paths fall beyond truncation levels $\alpha L_N$ and $\alpha L_{2N}$. Consequently, the strong convergence property for the forward approximation does not guarantee that the quantity $E[|T_{L_N}(g(X_N^T)) - T_{L_{2N}}(g(X_{2N}^T))|^2]^{1/2}$ decays with the rate $1/2$, as is shown in Figure 3. This lack of “good convergence” at the terminal time then translates into a deterioration of the convergence rate for the BSDE part of the scheme. Note that there is no contradiction with what is predicted by Theorem 4.3. Indeed, it is expected that for very large values of $N$ the asymptotic convergence will begin to take place.

For bigger values of $\alpha$ (between 40 and 60) we can finally observe the transition to the asymptotic regime happening in our window of $N$’s.

Finally for larger values of $\alpha$ (60 and above) we mark on Figure 2(b) only the finite values of $e(N)$ (defined in (7.1)). This shows in a rather clear fashion that if we do not truncate strongly enough (for a given value of $N$) the scheme “blows up” (the code produces NaN values). One also observes that the bigger the multiplying factor $\alpha$ the smaller the time-step must be in order to make sure that $e(N)$ decays appropriately (converges). This depicts very well the scenario described in our counter-example. We believe that the high convergence rates appearing in Table 2 when $\alpha$ is big is due to the smoothness of the driver $f$ we chose for example 2 (similar to example 1) and its

\[\text{In order to significantly increase } N \text{ we would also need to increase } M \text{ to levels that are beyond our computational capabilities.}\]
Figure 3: Convergence of the error $E\left[ |T_L N (g(X_N^N)) - T_L 2N (g(X_2^N))|^{2}\right]^{1/2}$ on the terminal condition, computed for $N \in \{20^i : i = 1, \cdots , 10\}$. Plot in log-log scale with different levels of truncation $L_N = \alpha L_h$, done with $M = 10^5$ and 10 simulations for each point. The estimated slopes are, for the corresponding multiplicative factors: $0.25, 0.17, -0.12, -0.29, -0.41, -0.50$ (reading the legend from top to bottom).

damping effect on the dynamics of the scheme. We leave an in-depth analysis of this fact for future research.

A Appendix

A.1 Motivating example

Before we state the main result we recall a result on the behavior of Gaussian random variables (which we do not prove, but the reader is invited to try, in any case see Lemma 4.1 in [HJK11]). The notation and probability spaces we work with in this Appendix are as stated in Section 2.

Lemma A.1. Let $(\Omega, F, P)$ be a probability space and let $Z : \Omega \to \mathbb{R}$ be an $F/B(\mathbb{R})$-measurable mapping with standard normal distribution. Then for any $x \in [0, \infty)$ it holds that

$$P(|Z| \geq x) \geq \frac{1}{4}xe^{-x^2}.$$

The statement of Lemma 1.1 follows from the next lemma.

Lemma A.2. Let $\pi N$ denote the uniform grid of the time interval $[0, 1]$ with $N + 1$ points and step size $h := 1/N$, where $N \in \mathbb{N}$. Define the driver $f(y) := -y^3$ and the terminal condition $\xi \in L_p(F_1)$ for any $p \geq 2$. Let $(Y, Z)$ be the unique solution to (1.3). Denote by $\{Y_i^{(N)}\}_{i \in \{0, \cdots , N\}}$ the Euler approximation of $(Y_i)_{i \in [0, 1]}$ defined via (1.4) over the grid $\pi N$.

Assume that $N$ is fixed and that $\xi$ verifies $|\xi| \geq 2\sqrt{N}$ $P$-a.s. then

i) for any $i \in \{0, \cdots , N\}$ it holds that $|Y_i| \geq 2^{3N-i}\sqrt{N}$. 

Assume now that $N$ is an even number (hence $t = 1/2$ is common to all grids $\pi^N$) and denote by $Y_{t}^{(N)}$ the approximation at the time point $t = 1/2$ (corresponding to $i = N/2$). Define $\xi$ as $\xi := W_{1/2} \in L^p(F_t) \setminus L^\infty(F_t)$ for any $p \geq 1$.

ii) For any $i \in \{N/2, \ldots, N\}$, on the set $\{\omega: \xi(\omega) \geq 2\sqrt{N}\}$ it holds that $|Y_i(\omega)| \geq 2^{2^{N-i}} \sqrt{N}$.

iii) moreover, $\lim_{N \to \infty} \mathbb{E}[|Y_{t}^{(N)}|] = +\infty$.

Proof. For the given $f$ and $\xi$ the results from Section 2 in [Par99] combined with the a priori estimates stated in our Section 2 ensure the existence and uniqueness of a solution $(Y, Z) \in S^p \times H^p$ to BSDE (1.3) for any $p \geq 2$. We now fix $N$ and drop the superscript $(N)$ from $Y^{(N)}$.

Proof of Part i) Without loss of generality assume that $\xi = Y_N \geq 2\sqrt{N}$. Then

$$Y_{N-1} = \mathbb{E}_{N-1}[Y_N - Y_{N}^{3}h] = \mathbb{E}_{N-1}[Y_N(1 - Y_{N}^{3}h)].$$

Observe that $Y_{N}^{3} \geq 2N$ which implies $(1 - Y_{N}^{3}h) \leq (1 - 2^2) < 0$. Hence (since $Y_N > 0$)

$$Y_{N-1} = \mathbb{E}_i[Y_N(1 - Y_{N}^{3}h)] \leq -2\sqrt{N}(2^2 - 1) \leq -2^2\sqrt{N}.$$

Next (since $Y_{N-1} < 0$) $Y_{N-1}^{2} \geq 2^4N$ which implies $1 - Y_{N-1}^{2}h \leq (1 - 2^4) < 0$. Hence

$$Y_{N-2} = \mathbb{E}_i[Y_{N-1}(1 - Y_{N-1}^{2}h)] = \mathbb{E}_i[(1 - Y_{N-1})(Y_{N-1}^{2}h - 1)] \geq 2^2\sqrt{N}(2^4 - 1) \geq 2^2\sqrt{N}.$$

Proceeding by induction we can show that

$$|Y_i| \geq 2^{2^{N-i}} \sqrt{N}.$$

Indeed, assume $|Y_{i+1}| \geq 2^{2^{N-i}} \sqrt{N}$ (in the light of above calculations; the negative case is analogous), then

$$Y_i = \mathbb{E}_i[Y_N(1 - Y_{N}^{3}h)] \leq 2^{2^{N-i-1}} \sqrt{N} \left( (2^{2^{N-i-1}})^2 - 1 \right) \leq 2^{2^{N-i}} \sqrt{N}$$

and statement i) is proved.

Before proving ii) and iii) we remark that no conditional expectation needs to be computed for the scheme (1.4) for $i \in \{N/2, \ldots, N\}$ because $\xi = W_{1/2}$ is $F_t$-adapted for any $t \in [1/2, 1]$. The scheme’s approximations up to $Y_{t}^{(N)}$ can be written as

$$Y_{N}^{(N)} = W_{1/2}, \quad Y_{N-1}^{(N)} = \psi(W_{1/2}), \quad Y_{N-2}^{(N)} = \psi(\psi(W_{1/2})), \ldots, \quad Y_{N}^{(N)} = \psi(\psi(\psi(\cdots(W_{1/2})))).$$

where $\psi(x) := x - hx^3$ and $\psi^{(n)}$ denotes the composition of $\psi$ with itself $n$-times ($n \in \mathbb{N}$).

Proof of Part ii) We work on the event that $\xi = Y_N \geq 2\sqrt{N}$. We have first

$$Y_{N-1} = \mathbb{E}_{N-1}[Y_N - Y_{N}^{3}h] = Y_N(1 - Y_{N}^{3}h).$$

Observe that $Y_{N}^{3} \geq 2^2N$ which implies $(1 - Y_{N}^{3}h) \leq (1 - 2^2) < 0$. Hence (since $Y_N > 0$)

$$Y_{N-1} = Y_N(1 - Y_{N}^{3}h) \leq -2\sqrt{N}(2^2 - 1) \leq -2^2\sqrt{N} < 0.$$

Next, since $Y_{N-1} < 0$, $Y_{N-1}^{2} \geq 2^4N$ which implies $1 - Y_{N-1}^{2}h \leq (1 - 2^4) < 0$. Hence

$$Y_{N-2} = Y_{N-1}(1 - Y_{N-1}^{2}h) = -Y_{N-1}(Y_{N-1}^{2}h - 1) \geq 2^2\sqrt{N}(2^4 - 1) \geq 2^2\sqrt{N}.$$
Proceeding by induction we can easily show that
\[ |Y_i| \geq 2^{2^{N-1}} \sqrt{N}, \quad i = \frac{N}{2}, \ldots, N. \]
Indeed, assume \( Y_{i+1} \geq 2^{2^{N-1}} \sqrt{N} \) (note that in the light of the above calculations the negative case is analogous). Then
\[ Y_i = Y_{i+1}(1 - Y_{i+1}^2) \leq 2^{2^{N-1}} \sqrt{N} \left( 1 - (2^{2^{N-1}})^2 \right) \leq -2^{2^{N-1}} \sqrt{N}. \]

**Proof of Part iii):** It follows easily from Lemma A.1 that
\[ P \left[ |W_{\frac{1}{2}}| \geq 2\sqrt{N} \right] \geq \frac{\sqrt{2}}{2} \sqrt{N} e^{-8N}. \]

Then, using Part i) (to go from the 1st to the 2nd line) and the above remark (on the 3rd line) we have
\[
\lim_{N \to \infty} E[|Y(N)|] = \lim_{N \to \infty} E[1_{\{\xi \geq 2\sqrt{N}\}}|Y_{\frac{1}{2}}(N)| + 1_{\{\xi < 2\sqrt{N}\}}|Y_{\frac{1}{2}}(N)|] \geq \lim_{N \to \infty} E[1_{\{\xi \geq 2\sqrt{N}\}}|Y_{\frac{1}{2}}(N)|] \\
\geq \lim_{N \to \infty} E[1_{\{\xi \geq 2\sqrt{N}\}}2^{2^{N-2}} \sqrt{N}] \\
= \lim_{N \to \infty} 2^{2^{N-2}} \sqrt{N} P[|W_{\frac{1}{2}}| \geq 2\sqrt{N}] \geq \lim_{N \to \infty} 2^{2^{N-2}} \sqrt{N} e^{-8N} = +\infty.
\]

\[ \square \]

### A.2 Basics of Malliavin’s calculus

We briefly introduce the main notation of the stochastic calculus of variations also known as Malliavin’s calculus. For more details, we refer the reader to [Nua06], for its application to BSDEs we refer to [Imk08]. Let \( S \) be the space of random variables of the form
\[ \xi = F\left(\int_0^T h_1^i dW_s^i, \ldots, \int_0^T h_n^i dW_s^i, 1 \leq i \leq n\right), \]
where \( F \in C^\infty(\mathbb{R}^{n \times d}), h_1, \ldots, h_n \in L^2([0, T]; \mathbb{R}^d), n \in \mathbb{N}. \) To simplify notation, assume that all \( h^j \) are written as row vectors. For \( \xi \in S, \) we define \( D = (D^1, \ldots, D^d) : S \to L^2(\Omega \times [0, T])^d \) by
\[ D^i_\theta \xi = \sum_{j=1}^n \frac{\partial F}{\partial x_{ij}} \left( \int_0^T h_1^j dW_t, \ldots, \int_0^T h_n^j dW_t \right) h_\theta^j, \quad 0 \leq \theta \leq T, \quad 1 \leq i \leq d, \]
and for \( k \in \mathbb{N} \) its \( k \)-fold iteration by \( D^{(k)} = (D^{(1)}, \ldots, D^{(k)})_{1 \leq i_1, \ldots, i_k \leq d}. \) For \( k \in \mathbb{N}, p \geq 1 \) let \( \mathbb{D}^{k,p} \) be the closure of \( S \) with respect to the norm
\[ \|\xi\|_{k,p}^p = \mathbb{E}\left[ \|\xi\|_{L^p}^p \right] + \sum_{i=1}^k \|D^{(k)}\xi\|_{(L^p)^i}^p. \]

\( D^{(k)} \) is a closed linear operator on the space \( \mathbb{D}^{k,p}. \) Observe that if \( \xi \in \mathbb{D}^{1,2} \) is \( \mathcal{F}_t \)-measurable then \( D_\theta \xi = 0 \) for \( \theta \in (t, T]. \) Further denote \( \mathbb{D}^{k,\infty} = \bigcap_{p>1} \mathbb{D}^{k,p}. \)

We also need Malliavin’s calculus for \( \mathbb{R}^m \) valued smooth stochastic processes. For \( k \in \mathbb{N}, p \geq 1, \) denote by \( \mathbb{L}_{k,p}(\mathbb{R}^m) \) the set of \( \mathbb{R}^m \)-valued progressively measurable processes \( u = (u^1, \ldots, u^m) \) on \([0, T] \times \Omega \) such that
i) For Lebesgue-a.a. \( t \in [0, T] \), \( u(t, \cdot) \in (\mathbb{D}^{k,p})^m \);

ii) \( [0, T] \times \Omega \ni (t, \omega) \mapsto D^{(k)}u(t, \omega) \in (L^2([0, T]^{1+k}))^{d \times n} \) admits a progressively measurable version;

iii) \( \|u\|_{k,p}^p = \|u\|_{H^p}^p + \sum_{i=1}^k \| D^i u \|_{(H^p)^{1+i}}^p < \infty \).

Note that Jensen’s inequality gives\(^1\) for all \( p \geq 2 \)

\[
\mathbb{E} \left[ \left( \int_0^T \int_0^T |D_u X_t|^2 du dt \right)^{\frac{p}{2}} \right] \leq T^{p/2-1} \int_0^T \| D_u X \|_{H^p}^p du.
\] (A.1)

We recall a result from [Imk08] concerning the rule for the Malliavin differentiation of Itô integrals which is of use in applications of Malliavin’s calculus to stochastic analysis.

**Theorem A.3** (Theorem 2.3.4 in [Imk08]). Let \((X_t)_{t \in [0,T]} \in \mathcal{H}^2\) be an adapted process and define \( M_t := \int_0^t X_r dW_r \) for \( t \in [0, T] \). Then, \( X \in \mathbb{L}^{1,2} \) if and only if \( M_t \in \mathbb{D}^{1,2} \) for any \( t \in [0, T] \).

Moreover, for any \( 0 \leq s, t \leq T \) we have

\[
D_s M_t = X_s \mathbb{1}_{\{s \leq t\}}(s) + \mathbb{1}_{\{s \leq t\}}(s) \int_s^t D_u X_r dW_r.
\] (A.2)

### A.3 A particular Gronwall lemma

We state here a “discrete Gronwall lemma” of some kind, particularly useful for the numerical analysis of BSDEs, and which we use extensively in this work.

**Lemma A.4.** Let \( a_i, b_i, c_i \) be such that \( a_i, b_i \geq 0, c_i \in \mathbb{R} \) for \( i = 0, 1, \ldots, N \). Assume that, for some constant \( c > 0 \) and \( h > 0 \), we have

\[
a_i + b_i \leq (1 + ch)a_{i+1} + c_i, \quad \text{for} \quad i = 0, 1, \ldots, N - 1.
\] (A.3)

Then the following inequality holds for every \( i \)

\[
a_i + \sum_{j=i}^{N-1} b_j \leq e^{c(N - i)h}a_N + \sum_{j=i}^{N-1} e^{c(j - i)h}c_j.
\]

**Proof.** The estimate is clearly true for \( i = N - 1 \) (even for \( i = N \) in fact). Then, for any \( i \leq N - 2 \), if it is true for \( i + 1 \), by multiplying both sides by \( e^{ch} \) we find that

\[
e^{ch}a_{i+1} + e^{ch} \sum_{j=i+1}^{N-1} b_j \leq e^{c(N-i)h}a_N + \sum_{j=i+1}^{N-1} e^{c(j-i)h}c_j
\]

Summing this inequality with (A.3) and noting that \( \sum_{j=i+1}^{N-1} b_j \leq e^{ch} \sum_{j=i+1}^{N-1} b_j \) due to the positivity of the \( b_j \) terms gives the sought estimate for any \( i \). \( \square \)

---

\(^{1}\) The reason behind this last inequality is that within the BSDE framework the usual tools to obtain a priori estimates yield with much difficulty the LHS while with relative ease the RHS.
