ABSTRACT
Graph pattern matching has been widely used in e.g., social data analysis. A number of matching algorithms have been developed that, given a graph pattern Q and a graph G, compute the set $M(Q,G)$ of matches of Q in G. However, these algorithms often return an excessive number of matches, and are expensive on large real-life social graphs. Moreover, in practice many social queries are to find matches of a specific pattern node, rather than the entire $M(Q,G)$.

This paper studies top-k graph pattern matching. (1) We revise graph pattern matching defined in terms of simulation, by supporting a designated output node $u_o$. Given G and Q, it is to find those nodes in $M(Q,G)$ that match $u_o$, instead of the large set $M(Q,G)$. (2) We study two classes of functions for ranking the matches: relevance functions $\delta_1()$ based on, e.g., social impact, and distance functions $\delta_2()$ to cover diverse elements. (3) We develop two algorithms for computing top-k matches of $u_o$ based on $\delta_1()$, with the early termination property, i.e., they find top-k matches without computing the entire $M(Q,G)$. (4) We also study diversified top-k matching, a bi-criteria optimization problem based on both $\delta_1()$ and $\delta_2()$. We show that its decision problem is NP-complete. Nonetheless, we provide an approximation algorithm with performance guarantees and a heuristic one with the early termination property. (5) Using real-life and synthetic data, we experimentally verify that our (diversified) top-k matching algorithms are effective, and outperform traditional matching algorithms in efficiency.

1. INTRODUCTION
Graph pattern matching is being widely used in social network analysis [5,32], among other things. A number of algorithms have been developed for graph pattern matching that, given a graph pattern Q and a graph G, compute $M(Q,G)$, the set of matches of Q in G (e.g., [11,18]).

Social data analysis, however, introduces new challenges to graph pattern matching. Social graphs are typically large, with millions of nodes and billions of edges. This gives rise to the following problems with the matching algorithms.

(1) The matching algorithms often return an excessive number of results. Indeed, when matching is defined by subgraph isomorphism [14], $M(Q,G)$ may contain exponentially many subgraphs of G; when graph simulation is adopted, $M(Q,G)$ is a relation of size $O(|G||Q|)$ [18], which may be larger than graph G. It is a daunting task for the users to inspect such a large $M(Q,G)$ and find what they are searching for.

(2) The sheer size of social graphs makes matching costly: for matching defined by simulation, it takes $O(|G||Q|+|G|^2)$ time to compute $M(Q,G)$ [11]; for subgraph isomorphism, it is NP-complete to decide whether a match exists (cf. [29]).

(3) Social queries often need to find matches of a specific pattern (query) node $u_o$ as “query focus” [3], i.e., we just want those nodes in a social graph G that are matches of $u_o$ in $M(Q,G)$, rather than the entire set $M(Q,G)$ of matches of Q. Indeed, this is how “graph search” (http://www.facebook.com/about/graphsearch) of Facebook is conducted on a big social graph with more than 1 billion users and 140 billion links [http://newsroom.fb.com/]. The need for this is also evident in, e.g., egocentric search [6] and expert recommendation [27,31]. In fact, 15% of social queries are to find matches of specific pattern nodes [27].

These highlight the need for top-k graph pattern matching: given Q, G and a designated pattern node $u_o$, it is to find top-k matches of $u_o$ in $M(Q,G)$, ranked by a quality function. The users only need to check k matches of $u_o$ instead of $M(Q,G)$. Better still, if we have an algorithm with the early termination property, i.e., it finds top-k matches of $u_o$ without computing the entire $M(Q,G)$, we do not have to pay the price of full-fledged graph pattern matching.

Example 1: A fraction of a collaboration network is given as graph G in Fig. 1. Each node in G denotes a person, with attributes such as job title, e.g., project manager (PM),
When graph pattern matching is defined in terms of subgraph isomorphism [29], no match of \( Q \) can be identified in \( G \). Indeed, it is too restrictive to define matches as isomorphic subgraphs [11]. Bisimulation [8] extends subgraph isomorphism with matching relations as equivalence relations, which is still unable to identify some sensible matches, e.g., \( \text{PM}_1 \). Instead, we adopt simulation [18] with a designated node, extending graph search by supporting both matching relations and a specified “query focus”. With graph simulation, \( M(Q,G) \) is a binary relation on the pattern nodes in \( Q \) and their matches in \( G \), including \( (\text{PM}_i, \text{PM}_j) \), \( (\text{DB}_i, \text{DB}_j) \), \( (\text{PRG}_i, \text{PRG}_j) \), \( (\text{ST}_i, \text{ST}_j) \) for \( i \in [1,4] \) and \( j \in [1,3] \).

Observe that \( M(Q,G) \) contains most of the nodes in \( G \) as matches, which are excessive since, e.g., the matches \( \text{ST}_i \), \( i \in [1,4] \) for \( \text{ST}_i \) are not required. However, what the user wants are the \( \text{PM} \) matches. It is hence unnecessary and too costly to compute the entire large set \( M(Q,G) \). Even for the output node \( \text{PM} \), too many \( \text{PM} \) are returned (\( i \in [1,4] \)).

We can do better with top-\( k \)-matching. When \( k = 2 \), we find two top-ranked \( \text{PM} \)'s that match \( PM \), and return them in response to the request, instead of \( M(Q,G) \). Better still, it is less costly. Indeed, while a naive algorithm for top-\( k \)-matching is to first compute \( M(Q,G) \) and then pick top-2 \( \text{PM} \)'s, an algorithm with the early termination property identifies the \( \text{PM} \)'s without computing the entire \( M(Q,G) \).

To rank the \( \text{PM} \)'s of \( \text{PM} \), one may consider the following criteria. (1) Social impact [21]. Observe that \( \text{PM}_2 \) can reach more people than any other \( \text{PM} \), i.e., \( \text{PM}_2 \) has collaborated with more people. Thus \( \text{PM}_2 \) has stronger social impact. (2) Social diversity [2, 35]. Consider match sets \( \{\text{PM}_1, \text{PM}_2\} \) and \( \{\text{PM}_2, \text{PM}_3\} \). While \( \text{PM}_2 \) and \( \text{PM}_3 \) worked with the same people, \( \text{PM}_1 \) and \( \text{PM}_2 \) are quite “dissimilar” since they covered different groups of people. Putting these together, \( \{\text{PM}_1, \text{PM}_2\} \) makes a good candidate for top-2 matches in terms of both social impact and diversity.

This example shows that top-\( k \)-graph pattern matching may rectify the limitations of existing matching algorithms. To make practical use of it, however, several questions have to be answered. How can specific output nodes be incorporated into graph pattern matching? What types of diversity functions should be used to rank the matches? What is the cost of computing top-\( k \) matches based on one or both of the functions? How can we guarantee early termination by our algorithms for computing top-\( k \) matches?

Contributions. This paper answers these questions. We focus on graph pattern matching defined by graph simulation, which has proved useful in social data analysis [5, 32].

(1) We revise the traditional notion of graph pattern matching by designating an output node \( u_o \) (Section 2). Given \( Q \) and \( G \), it is to compute \( M_o(Q,G, u_o) \), the set of matches of \( u_o \) in \( G \) via \( Q \). That is, the set of nodes in \( G \) that are in \( M(Q,G) \) and moreover, match the output pattern node \( u_o \).

(2) We study two cases of functions to rank matches of \( u_o \) (Section 3), namely, relevance functions \( \delta_i() \) that measure the relevance of a match, and distance functions \( \delta_k() \), which measure the “dissimilarity” of two matches. Based on both, we define a bi-criteria (balanced by a parameter \( \lambda \) diversification function \( F() \), which aims both to maximize social impact and to cover social elements as diverse as possible. To simplify the discussion, we focus on two simple relevance and distance functions. Nonetheless, we show that our techniques support a range of such functions used in practice.

(3) We investigate top-\( k \)-graph pattern matching (Section 4). Given a graph pattern \( Q \), a graph \( G \) and a positive integer \( k \), it is to find \( k \) top-ranked matches of \( u_o \) based on the relevance function \( \delta_i() \). We provide two algorithms for doing so, in \( O(|G||Q| + |G|^2) \) time yet with the early termination property [10]. That is, they stop as soon as the top-\( k \) matches are found, without computing the entire \( M(Q,G) \).

(4) We also study the diversified top-\( k \)-graph pattern matching problem (Section 5). It is to find top-\( k \) matches of \( u_o \) based on the diversification function \( F() \). We show that its decision version is \( \text{NP} \)-complete. The bi-criteria optimization problem is also hard to approximate, as suggested in [4] (see more in Section 5). Despite this, we develop an approximation algorithm in time \( O(|Q||G| + |G|^2) \) with approximation ratio \( 2 \). We also give a heuristic algorithm in time \( O(|Q||G| + |G|^2) \), with the early termination property.

(5) Using both real-life and synthetic data, we experimentally verify the efficiency and effectiveness of our methods (Section 6). We find that they effectively reduce excessive matches: when \( k = 10 \), our top-\( k \) matching methods only need to examine 40% - 45% of matches in \( M(Q,G) \) on average, and our diversified top-\( k \) heuristic finds high-quality matches by inspecting 45% of the matches. Better still, our algorithms are more efficient than their traditional counterparts, improving the efficiency by 64% (resp. 48%) on average for acyclic (resp. cyclic) patterns. In addition, they scale well with \( |Q|, |G| \) and \( k \), and are not sensitive to the change of \( \lambda \). These verify that our methods indeed remedy the limitations of traditional matching, to an extent.

These results yield a promising approach to querying social data. In the worst case, our (diversified) top-\( k \)-matching algorithms have the same complexity \( O(|G||Q| + |G|^2) \) as traditional matching algorithms, despite the extra computation introduced for ranking and diversifying matches. Better still, they have the early termination property and hence, perform better than the traditional algorithms in efficiency, as verified analytically and experimentally. All the proofs, algorithms and complexity analyses can be found in [1].

Related work. We categorized the related work as follows.

Top-\( k \) queries. There has been a host of work on top-\( k \) query answering for relational data, XML and graphs.

Relational databases. Top-\( k \) query answering is to retrieve top-\( k \) tuples from query result. Given a monotone scoring function and sorted lists, one for each attribute, Fagin’s algorithm [9] reads attributes from the lists and constructs tuples with the attributes. It stops when \( k \) tuples are constructed from the top-ranked attributes that have been seen. It then performs random access to find missing scores. It is
optimal with high probability for some monotone scoring functions. Extending Fagin’s algorithm, the threshold algo-

2.1 Data Graphs and Pattern Graphs

Data graphs. A data graph (or simply a graph) is a di-

Pattern graphs. A pattern graph is a directed graph Q =

Graph simulation [18]. A graph G matches a pattern Q if there exists a binary relation S ⊆ Vp × V such that (1) for each node u ∈ Vp, there exists a node v ∈ V such that (u, v) ∈ S, referred to as a match of u; (2) for each pair (u, v) ∈ S, (a) fQ(u) = L(v), and (b) for each edge (u′, v′) in Ep, there exists an edge (u′, v′) in G such that (u′, v′) ∈ S.

It is known that if G matches Q, then there exists a unique maximum relation M(Q, G) [18]. If G does not match Q, M(Q, G) is the empty set. This maximum relation M(Q, G) is referred to as the set of matches of Q in G. The relation M(Q, G) can be depicted as the result graph of Q in G [11].

Example 2: Example data graph G and pattern Q are given in Fig. 1. One may verify that G matches Q, with the unique, maximum match M(Q, G) given in Example 1. The label fQ(u) of a query node u specifies a search condition: a node v in G can match u only if L(v) = fQ(u).

 Given G and Q, the traditional notion of graph pattern matching by simulation is to compute M(Q, G). It is known that M(Q, G) can be computed in O((|Vp| + |V|)(|Ep| + |E|)) time [11], where |M(Q, G)| is bounded by O(|V|!|Vp|) [18].

We denote |Vp| + |Ep| as |Q| (the size of the pattern graph), and |V| + |E| as |G| (the size of the data graph).
2.2 Graph Pattern Matching Revised

We extend a pattern to be \( Q = (V_P, E_P, f_v, u_o) \), where \( u_o \) is a query node in \( V_P \) labeled with ‘\( u \)’, referred to as the output node of \( Q \), and \( V_P, E_P \) and \( f_v \) are the same as above.

Given a pattern \( Q \) and a graph \( G \), we define the matches of \( Q \) in \( G \) to be \( M_o(Q, G, u_o) = \{ v \mid (u_o, v) \in M(Q, G) \} \), i.e., the matches of the output node \( u_o \) in the unique maximum \( M(Q, G) \). Here \( M_o(Q, G, u_o) = \emptyset \) if \( G \) does not match \( Q \).

Note that \( M_o(Q, G, u_o) \) is smaller than \( M(Q, G) \): its size is bounded by \( |V| \) as opposed to \( |V'| |V'_P| \).

Example 3: Recall graph \( G \) and pattern \( Q \) from Example 1. The node \( P(M) \) is marked as the output node of \( Q \). Then the set \( M_o(Q, G, PM) = \{ PM_i \mid i \in [1, 4] \} \), which consists of 4 nodes as opposed to 15 node pairs in \( M(Q, G) \).

Graph pattern matching can be readily extended to support the following: (1) patterns (resp. graphs) with multiple predicates (resp. attributes) on its nodes, i.e., search conditions defined with multiple predicates; and (2) patterns with multiple output nodes. To simplify the discussion, we focus on a single designated output node in this paper, as commonly found in practice [27]. Nonetheless, the results of this work extend to patterns with multiple output nodes; the interested reader is invited to consult [1] for details.

3. RANKING PATTERN MATCHES

The result set \( M_o(Q, G, u_o) \) could still be excessively large when \( G \) is large, while users are often only interested in the best \( k \) matches of the output node of \( Q \) [19]. This suggests that we define certain functions to rank the matches, and compute top-\( k \) matches for \( u_o \) based on the functions.

In this section we study two sets of ranking functions: relevance functions to measure the relevance of matches (Section 3.1), and distance functions to measure match diversity (Section 3.2). We then define a diversification function, which is a bi-criteria objective function combining relevance and diversity (Section 3.3). Based on these, we introduce two top-\( k \) graph pattern matching problems. To simplify the discussion, we start with a simple formulation of the ranking functions based on “social impact”, and we generalize the problems to a variety of ranking functions (Section 3.4).

3.1 Relevant Matches

We start with a simple function to measure the relevance of the matches of \( u_o \). It is based on a notion of relevant sets.

Relevant set. Given a match \( v \) of a query node \( u \) in \( Q \), the relevant set of \( v \) w.r.t. \( u \) (denoted as \( R_{(u,v)} \)) includes all matches \( v' \) of \( u \) for each descendant \( u' \) of \( u \) in \( Q \), such that if \( u \) reaches \( u' \) via a path \( (u, u_1, \ldots, u_n, u') \), then \( v \) reaches \( v' \) via \( (v, v_1, \ldots, v_n, v') \), where \( (u_i, v_i) \in M(Q, G) \) \( i \in [1, n] \).

That is, \( R_{(u,v)} \) includes all matches \( v' \) to which \( v \) can reach via a path of matches. Following [11], one can verify the following, which shows that the relevant set is well-defined.

Lemma 1: Given a pattern graph \( Q \) and a data graph \( G \), if \( G \) matches \( Q \), then for any match \( v \) of a query node \( u \), there exists a unique, maximum relevant set \( R_{(u,v)} \).

Relevance function. On a match \( v \) of \( u \), we define the relevance function \( \delta_r(\cdot) \) in terms of the relevant set \( R_{(u,v)} \):

\[
\delta_r(u,v) = |R_{(u,v)}|.
\]

That is, the relevance function favors those matches that can reach more other matches: for a match \( v_o \) of the output node \( u_o \), the more matches \( v_o \) can reach, the bigger “impact” it may have, as observed in social network studies [20]. Thus, the matches with high \( \delta_r(\cdot) \) values are preferred for relevance.

Top-\( k \) matching problem. We now state the top-\( k \) matching problem, denoted by \( \text{topKP} \). Given a graph \( G \), a pattern \( Q \) with output node \( u_o \), and a positive integer \( k \), it is to find a subset \( S \subseteq M_o(Q, G, u_o) \), such that \( |S| = k \) and

\[
\delta_r(S) = \arg\max_{S' \subseteq M_o(Q, G, u_o) \mid |S'| = k} \sum_{v \in S'} \delta_r(u,v) = (S).
\]

Abusing \( \delta_r(\cdot) \), we also use \( \delta_r(S) \) to denote \( \sum_{v \in S} \delta_r(u,v) \), referred to as the relevance of \( S \) to \( u_o \).

That is, \( \text{topKP} \) is to identify a set of \( k \) matches of \( u_o \) that maximizes the total relevance to \( u_o \). In other words, for all \( S' \subseteq M_o(Q, G, u_o) \), if \( |S'| = k \) then \( \delta_r(S) \geq \delta_r(S') \).

Example 4: Recall \( G \) and \( Q \) from Fig. 1. The relevant sets of the matches in \( M_o(Q, G, PM) \) are shown below.

<table>
<thead>
<tr>
<th>match</th>
<th>relevant set</th>
</tr>
</thead>
<tbody>
<tr>
<td>PM_1</td>
<td>{ DB_2, PRG, ST_1, ST_2 }</td>
</tr>
<tr>
<td>PM_2</td>
<td>{ DB_2, DB_3, PRG, ST_3, ST_1 }</td>
</tr>
<tr>
<td>PM_3</td>
<td>{ DB_2, UB, PRG, ST_3, ST_1 }</td>
</tr>
<tr>
<td>PM_4</td>
<td>{ DB_2, UB, PRG, ST_3, ST_1 }</td>
</tr>
</tbody>
</table>

One may verify that \( S = \{ PM_2, PM_3 \} \) or \( S = \{ PM_2, PM_4 \} \) is a top-2 relevant match set, i.e., \( S \) reaches more matches in \( G \) than any other 2-match set for PM. The total relevance \( \delta_r(S) \) of \( \{ PM_2, PM_3 \} \) is 6, while \( \delta_r(S) \) of \( \{ PM_2, PM_4 \} \) is 8 + 6 = 14.

The need for studying \( \text{topKP} \) is evident: instead of inspecting possibly large set \( M_o(Q, G, u_o) \), we want to find top-\( k \) elements that are most relevant to our search.

3.2 Match Diversity

We next introduce a simple metric for result diversity [30]. As observed in [2, 33], it is important to diversify (social) search results to avoid repeated recommendations for similar elements (see Example 1), advocate elements in different groups and to cover elements with new information.

Diversity function. To characterize the diversity of a match set, we define a distance function to measure the “dissimilarity” of two matches. Given two matches \( v_1 \) and \( v_2 \) of a query node \( u \), we define their distance \( \delta_d(v_1, v_2) \) to be:

\[
\delta_d(v_1, v_2) = 1 - \frac{|R_{(u,v_1)} \cap R_{(u,v_2)}|}{|R_{(u,v_1)} \cup R_{(u,v_2)}|}.
\]

The distance function \( \delta_d(\cdot, \cdot) \) computes the number of distinct matches that two matches of \( u_o \) may impact. The larger \( \delta_d(v_1, v_2) \) is, the more dissimilar \( v_1 \) and \( v_2 \) are. It indicates the social diversity between the matches. Observe that the function constitutes a metric. For any matches \( v_1, v_2 \) and \( v_3 \) of \( u_o \), (1) \( \delta_d(v_1, v_2) = \delta_d(v_2, v_1) \), and (2) it satisfies the triangle inequality, i.e., \( \delta_d(v_1, v_3) \leq \delta_d(v_1, v_2) + \delta_d(v_2, v_3) \).

Example 5: Given \( G \) and \( Q \) in Fig. 1, we have the following: (1) \( \delta_d(PM_3, PM_4) = 0 \); this suggests that \( PM_3 \) and \( PM_4 \) have impact on exactly the same group of people in \( G \), i.e., they cannot be distinguished in terms of “social impact”; and (2) \( \delta_d(PM_2, PM_3) = \frac{1}{2}, \delta_d(PM_2, PM_4) = \frac{1}{4}, \delta_d(PM_1, PM_3) = 1 \). Thus \( PM_1 \) and \( PM_4 \) are most dissimilar to each other, as they are related to two completely different groups of people.

3.3 Match Diversification

It is recognized that search results should be relevant, and at the same time, be as diverse as possible [13, 35]. Based on \( \delta_r(\cdot) \) and \( \delta_d(\cdot) \) we next introduce a diversification function.
Diversification function. On a match set $S = \{v_0, \ldots, v_k\}$ of the output node $u_o$, the diversification function $F(\cdot)$ is defined as

$$F(S) = (1 - \lambda) \sum_{i \in S} \delta_i^\prime(u_o, v_i) + \frac{2 - \lambda}{k - 1} \sum_{i,j \in S, i < j} \delta_d(v_i, v_j),$$

where $\lambda \in [0, 1]$ is a parameter set by users, $\delta_i^\prime(u_o, v_i)$ is a normalized relevance function defined as $\delta_i^\prime(u_o, v_i) = C_{o,i}$, and $C_{o,i}$ is the total number of the candidates of all those query nodes $u^\prime$ to which $u_o$ can reach in $Q$. Here a node $v^\prime$ in $G$ is called a candidate of a query node $u^\prime$ if $L(v^\prime) = f_u(u^\prime)$, i.e., they share the same label. The diversity metric is scaled down with $\frac{2 - \lambda}{k - 1}$, since there are $\binom{k}{2}$ numbers for the difference sum, while only $k$ numbers for the relevance sum.

The function $F(\cdot)$ is a minor revision of max-sum diversification introduced by [13]. It is a bi-criteria objective function to capture both relevance and diversity. It strikes a balance between the two with a parameter $\lambda$ that is controlled by users, as a trade-off between the two [35].

Diversified top-$k$ matching problem. Based on the function $F(\cdot)$, we next state the diversified top-$k$ matching problem, denoted by $\text{topKDP}$. Given $G$, $Q$ with output node $u_o$, a positive integer $k$, and a parameter $\lambda \in [0, 1]$, it is to find a set of $k$ matches $S \subseteq M_o(Q, G, u_o)$ such that

$$F(S) = \arg\max_{S \subseteq S' \subseteq M_o(Q, G, u_o)} F(S'),$$

i.e., for all $k$-element sets $S' \subseteq M_o(Q, G, u_o)$, $F(S') \geq F(S)$. In contrast to $\text{topKP}$ that is to maximize relevance only, $\text{topKDP}$ is to find a set of $k$ matches from $M_o(Q, G, u_o)$ such that the bi-criteria diversification function is maximized.

Example 6: Recall graph $G$ and pattern $Q$ from Fig. 1. One can verify that (a) when $\lambda = 0$, i.e., when only relevance is considered, a top-2 set is $\{PM_2, PM_3\}$; and (b) when $\lambda = 1$, i.e., when the users only care about diversity, a top-2 set is $\{PM_1, PM_3\}$. Moreover, (c) when $\frac{2 - \lambda}{k - 1} < \lambda < 0.5$, $\{PM_1, PM_2\}$ makes a top-2 diversified match set, (d) when $\lambda < \frac{2 - \lambda}{k - 1}$, $\{PM_2, PM_3\}$ is the best choice; and (e) when $\lambda > 0.5$, $\{PM_1, PM_3\}$ turns out to be the best diversified match set.

3.4 Generalized Top-$k$ Matching

We next generalize $\delta_i^\prime(\cdot)$ and $\delta_d(\cdot)$ to define general relevance and distance functions, based on which we characterize generalized (diversified) top-$k$ matching problems.

Generalized ranking functions. For a match $v$ of a pattern node $u$, we use a generalized relevant set $R^*(u, v)$ to represent the set of descendants of $v$ in $G$ that are “relevant” to $u$ or its descendants (denoted as $R(u)$) in $Q$. We denote by $M(Q, G, R(\cdot))$ the matches of the nodes in $R(u)$.

(1) We consider a class of general relevance functions, which are arbitrary monotonic increasing polynomial-time computable (PTIME) functions defined in terms of $R(u)$ and $R^*(u, v)$. We refer to such functions as generalized relevance functions $\delta_i^\ast(u, v)$. Accordingly, the relevance function of a match set $S$, denoted by $\delta_i^\ast(S)$, is a monotonically increasing PTIME function of $\delta_i^\ast(u, v)$, for each $v \in S$.

(2) A generalized diversity function $\delta_d^\ast(v_1, v_2)$ of two matches $v_1$ and $v_2$ can be any PTIME computable function metric defined with $R^*(u, v_1)$ and $R^*(u, v_2)$. Given a match set $S$, the generalized diversification function $F^*(\cdot)$ is defined as

$$F^*(S) = (1 - \lambda)\delta_i^\ast(S) + \frac{2 - \lambda}{k - 1} \sum_{i,j \in S, i < j} \delta_d(v_i, v_j),$$

where $\lambda \in [0, 1]$ is a parameter set by users.

One may verify that $\delta_i^\ast(\cdot)$, $\delta_d^\ast(\cdot)$ and $F(\cdot)$ given earlier are special cases of $\delta_i^\ast(\cdot)$, $\delta_d^\ast(\cdot)$ and $F^*(\cdot)$, respectively. Moreover, $\delta_i^\ast(\cdot)$ and $\delta_d^\ast(\cdot)$ are able to express a variety of ranking functions commonly used in e.g., social/information networks [22, 24] and Web search [28], including the following:

Generalized top-$k$ matching. Given $Q$ with output node $u_o$, graph $G$ and an integer $k$, the generalized top-$k$ matching (resp. topKDP) problem is to find a subset $S \subseteq M_o(Q, G, u_o)$ of $k$ matches, which maximizes $\delta_i^\ast(S)$ (resp. $F^*(S)$).

Remarks. A function $f(S)$ over a set $S$ is called submodular if for any subset $S_1 \subseteq S_2 \subseteq S$ and $x \in S \setminus S_2, f(S_2 \cup \{x\}) - f(S_1) \geq f(S_2) - f(S_1)$. Note that our diversification functions are not necessarily submodular. For example, $F(\cdot)$ (Section 3.3) is not submodular. Indeed, one may verify that $F(S \cup \{v\}) - F(S) \leq f(S_2 \cup \{v\}) - f(S_2)$, although $F(\cdot)$ contains a submodular component $\delta_d^\ast(\cdot)$.

To simplify the discussion, we present algorithms for topKP (Section 3.1) and topKDP (Section 3.3). Nonetheless, we show that the algorithms can be readily extended to support generalized top-$k$ matching stated above.

4. FINDING TOP-$k$ MATCHES

We next develop several algorithms for solving the top-$k$ matching problem (topKP) in quadratic time.

The first one, referred to as Match, follows a “find-all-match” strategy. Given $Q$ with output node $u_o$, $G$ and $k$, (1) it first finds $M(Q, G)$ with the algorithms in e.g., [11,18]; (2) it then simply computes the relevance for all the matches of $u_o$, and selects $k$ most relevant matches. One may verify that the algorithm is in $O(|Q| + |V|(|V| + |E|))$ time.

This algorithm, however, always computes the entire $M(Q, G)$ and is costly for big $G$. We can rectify this by using “early termination” algorithms. In contrast to Match, these algorithms stop as soon as top-$k$ matches are identified, without computing the entire $M(Q, G)$.

Proposition 2: For given $Q$, $G$ and an integer $k$, topKP can be solved by early-termination algorithms.

These algorithms leverage a sufficient condition for early termination. For a query node $u$, we denote as $\text{can}(u)$ the set of all the candidates $v$ of $u$, i.e., $v$ has the same label as $u$. We use $l(u, v)$ and $h(u, v)$ to denote a lower bound and upper bound of $\delta_d^\ast(u, v)$, respectively, i.e., $l(u, v) \leq \delta_d^\ast(u, v) \leq h(u, v)$. Then one can easily verify the following.

Proposition 3: A $k$-element set $S \subseteq \text{can}(u_o)$ is a set of top-$k$ matches of $u_o$ if (1) each $v$ in $S$ is a match of $u_o$ and (2) $\min_{v \in S}(l(u_o, v)) \geq \max_{v \in S} h(u_o, v)$.\]}

That is, the smallest lower bound of the matches in $S$ is no less than the largest upper bound of those in $\text{can}(u_o)$, $S$. We use this condition to decide whether $S$ is a top-$k$ match set.
Input: A DAG pattern \( Q = (V_p, E_p, f_v, u_0) \), data graph \( G \), and a positive integer \( k \).
Output: A top-\( k \) match set of \( u_0 \).
1. min-heap \( S := \emptyset \); termination := false;
2. for each \( u \in V_p \) do
3. compute topological rank \( r(u) \); initialize \( \text{can}(u) \);
4. for each \( v \in \text{can}(u) \) do initialize \( v.T \);
5. while (termination = false) do
6. select a set of unvisited candidates \( S \subseteq \text{can}(u) \) of query nodes \( u \in Q \), where \( r(u) = 0 \);
7. if \( S \neq \emptyset \) then
8. \( (G, S) := \text{AcyclicProp}(Q, S, G, S) \);
9. check the termination condition and update termination;
10. else termination := true;
11. return \( S \);

Figure 2: Algorithm TopKDAG

We also use the notion of ranks. For a graph \( G \), the strongly connected component graph \( G_{\text{SCC}} \) is a DAG obtained by collapsing each strongly connected component SCC of \( G \) into a single node. We use \( v_{\text{SCC}} \) to denote the SCC node containing \( v \) and \( E_{\text{SCC}} \) as the set of edges between SCC nodes. The topological rank \( r(v) \) of a node \( v \) in \( G \) is defined as (a) \( r(v) = 0 \) if \( v_{\text{SCC}} \) is a leaf in \( G_{\text{SCC}} \) (i.e., with outdegree 0), and otherwise, (b) \( r(v) = \max(1+r(v')) \) (\( v_{\text{SCC}}, v_{\text{SCC}}' \in E_{\text{SCC}} \)).

Based on these notations and Proposition 3, we provide two algorithms for topKDAG as a constructive proof of Prop. 2, when \( Q \) is a DAG pattern (Section 4.1) and a cyclic pattern (Section 4.2), respectively. The detailed proofs are in [1].

4.1 Algorithm for Acyclic Patterns

We start with an algorithm for topKP when \( Q \) is a DAG pattern, denoted as TopKDAG. To simplify the discussion, we assume that the output node \( u_0 \) is a “root” of \( Q \), i.e., it has no parent, and it can reach all the query nodes in \( Q \). We will discuss the case for “non-root” \( u_0 \) shortly.

We use the condition given in Proposition 3 to achieve early termination. For each candidate \( v \) of a query node \( u \) in \( Q \), TopKDAG dynamically maintains a vector \( v.T \), which contains (1) a Boolean equation \( v.\text{bf} \) of the form \( X_v = f \), where \( f \) is a Boolean formula that indicates whether \( v \) is a match of \( u \); (2) a subset \( v.R \) of its relevant set \( R(u,v) \) and (3) integers \( v.l \) and \( v.h \) to estimate the lower and upper bound of \( \delta(u,v) \), respectively. Instead of computing \( M(Q,G) \), TopKDAG computes a set of matches for some query nodes, and iteratively updates the vectors of the other candidates by “propagating” the partially evaluated results.

Algorithm. Algorithm TopKDAG is shown in Fig. 2. It has two stages: initialization and propagation, given as follows.

(1) Initialization (lines 1-4). TopKDAG first initializes (a) a min-heap \( S \) to maintain the matches of \( u_0 \), ranked by \( v.l \), and (b) a Boolean variable termination for the termination condition (line 1). For each query node \( u \) in \( Q \), it then computes its topological rank \( r(u) \), initializes data structures for all the candidates of \( u \) (lines 2-4).

The vector \( v.T \) is initialized as follows (line 4). For each candidate \( v \) of \( u_0 \), (1) if \( r(u) = 0 \), then \( v.T \) is already a match, thus TopKDAG sets \( v.\text{bf} = X_v = \text{true} \), \( v.R = \emptyset \), and \( v.l = v.h = 0 \); (2) otherwise, \( v.R = \emptyset \), \( v.l = 0 \), and \( v.\text{bf} \) is set as \( X_v = \bigwedge_{u_i \in E_p} (\bigvee_{v_j \in \text{can}(u_i)} X_{v_j}) \), for each child \( v_i \) of \( v \). Intuitively, \( X_v \) is true iff for each child \( u_i \) of \( v \), \( v \) has a child \( v_i \) that matches \( u_i \). In addition, \( v.h = c(u_0) \) (Section 3).

(2) Propagation (lines 5-10). In the propagation, TopKDAG (1) checks whether some candidates become matches of \( u_0 \), and (2) updates the lower and upper bounds of the candidates, until either the termination condition is satisfied, or all the matches are identified. It iteratively propagates the known matches and their relevance to evaluate Boolean equations of candidates, and adjusts their lower and upper bounds. Using a greedy heuristic, it selects a set \( S \) of candidates of query nodes ranked 0 (line 6), which is a minimal set that includes all the children of those candidates of query nodes with rank 1. Note that \( S \) is already a match set since each node in \( S \) is a leaf. If \( S \) is not empty, i.e., there exist unvisited matches (line 7), TopKDAG then propagates \( v.T \) to all the ancestors \( v' \) of \( v \) and updates \( v'.T \) and \( S \), by invoking procedure AcyclicProp (line 8). If the condition specified in Prop. 3 holds, or if \( S \) is empty, termination is set true (line 9-10). It returns \( S \) as the result (line 11).

Procedure AcyclicProp. Given a set \( S \) of matches, AcyclicProp (not shown) updates \( G \) and \( S \) as follows. For each match \( v \) of \( u \) in \( G \), where \( X_v = \text{true} \), and for each pattern edge \( (u',u) \), it identifies all the parents \( v' \) of \( v \) that are candidates of \( u' \), and updates \( v'.T \) as follows: (1) \( v'.\text{bf} \) is re-evaluated with \( X_v = \text{true} \); (2) if \( v'.\text{bf} \) becomes true, then for each child \( v'' \) of \( v' \) of which \( X_{v''} = \text{true} \), \( v''.R := v'.R \cup v''.R \cup v'.T \); (3) if \( X_{v''} = \text{true} \), \( v''.l \) is set as \( \{v'.R\} \) after \( v''.R \) is updated; intuitively, only when \( v \) is determined to be a match, its lower bound can be “safely” estimated by \( v'.R \); (4) \( v'.h \) is set to be \( \{v'.R\} \) as soon as for all children \( v'' \) of \( v' \), none of \( v''.h \) is changed further; and (5) if \( v'.\text{bf} \) no longer has Boolean variables that are not instantiated, \( v.l = v.h \), i.e., \( R(v,u) \) is determined now. If \( v'.T \) is updated, \( v' \) is added in a queue for further propagation.

During the process, AcyclicProp inserts a new match \( v \) into the min-heap \( S \) if it has less than \( k \) matches, or replaces a match \( v'' \) in \( S \) with \( v' \), which is a new match of \( u_0 \) and is not in \( S \), if \( v'.l > v''.h \). It then returns updated \( S \) and \( G \).

Example 7: Consider graph \( G \) given in Fig. 1 and a DAG pattern \( Q_1 \) with edge set \( \{PM(DB), (PM, PRG), (PRG, DB)\} \), where \( u_0 = PM \). When \( Q_1 \) is issued on \( G \), TopKDAG identifies the top-1 match for \( u_0 \) as follows.

(1) For initialization (lines 1-4), TopKDAG sets the vectors \( v.T := (v.\text{bf}, v.R, v.l, v.h) \) for (parts of) candidates as follows.

<table>
<thead>
<tr>
<th>( v.T )</th>
<th>( v.l = c(u_0) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>PM2</td>
<td>( X_{PM2} = (X_{PM1}, X_{PM1} \land X_{DB}, \emptyset, 0, 0) )</td>
</tr>
<tr>
<td>PM3</td>
<td>( X_{PM3} = (X_{PM2} \land X_{DB}, \emptyset, 0, 0) )</td>
</tr>
<tr>
<td>PM4</td>
<td>( X_{PM4} = (X_{PM3}, 0, 0, 0) )</td>
</tr>
</tbody>
</table>

(2) In the propagation stage, AcyclicProp selects \( S \) as e.g., a candidate \( DB_2 \) for the query node DB ranked 0 in \( Q_1 \). Then it starts the propagation, which updates the vectors as:

<table>
<thead>
<tr>
<th>( v.T )</th>
<th>( v.l = c(u_0) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>PM2</td>
<td>( X_{PM2} = (X_{PM1}, X_{PM1} \land X_{DB}, \emptyset, 0, 0) )</td>
</tr>
<tr>
<td>PM3</td>
<td>( X_{PM3} = (X_{PM2} \land X_{DB}, \emptyset, 0, 0) )</td>
</tr>
<tr>
<td>PM4</td>
<td>( X_{PM4} = (X_{PM3}, 0, 0, 0) )</td>
</tr>
</tbody>
</table>

One can verify that \( PM4 \) is determined to be a match of \( PM \) after a single iteration. Better still, the early termination condition is satisfied: \( PM4 \) is 3, which is already the largest relevance value. Hence, TopKDAG returns \( PM4 \) directly.

Correctness. Algorithm TopKDAG correctly computes \( S \) as a top-\( k \) match set for \( u_0 \) based on \( \delta() \). (1) It always terminates. In each while iteration (lines 5-10), a set of unvisited candidates \( S \) is checked. TopKDAG terminates
either when the termination condition is true, or when $S_e$ is empty, i.e., all matches have been found. (2) TopKDAG returns $S$ that consists of either top-k matches by Prop. 3, or all matches of $u_v$ when $u_v$ has less than $k$ matches.

**Complexity.** The initialization (lines 1-4) takes $O(|Q||G|)$ time, by using an index. For each node $v$ in $G$, the index records the numbers of its descendants with a same label, and efficiently estimates $v.h$ by aggregating the numbers. It takes in total $O(V(|V| + |E|))$ time to propagate changes and update vectors (lines 5-10). Min-heap $S$ can be maintained in $O(|V| \log k)$ time in total (line 8). Checking early termination can be done in $O(1)$ time (line 9), by using a max-heap to record the upper bounds of those candidates of $u_v$. Thus TopKDAG takes $O(|Q||G| + |V||V| + |E| + |V| \log k)$ time in the worst case, i.e., $O(|Q||G| + |V||V| + |E|)$ as $\log k$ is often far smaller than $Q$ (see [1] for details).

**Early termination.** Algorithm TopKDAG has the early termination property. More specifically, it combines the evaluation and ranking in a single process, and terminates as soon as top-k matches are identified based on Proposition 3. That is, it computes top-k matches for $u_v$ without computing and sorting the entire $M_u(Q, G, u_v)$. As will be verified in Section 6, while TopKDAG has the same worst-case complexity as Match, it substantially outperforms Match.

Algorithm TopKDAG can also be extended to support $u_v$ that is not a root node. Besides the termination condition (Prop. 3), it simply checks whether there exists a match for all query nodes in $Q$. One can verify that the correctness and complexity results hold for the extended TopKDAG, as well as the early termination property (see [1] for details).

### 4.2 Algorithm for Cyclic Patterns

To cope with a cyclic pattern $Q$, we next provide an algorithm for TopKP, denoted as TopK, by extending TopKDAG. Given $Q$, TopKP first computes the strongly connected component graph $Q_{SCC}$ of $Q$ (Section 4.1). Treating $Q_{SCC}$ as a DAG pattern, it then conducts initialization and bottom-up propagation along the same lines as TopKDAG. It terminates as soon as the condition of Proposition 3 is satisfied.

In contrast to TopKDAG, however, TopK has to deal with nontrivial nodes in $Q$, i.e., those nodes whose corresponding SCC node $u_{SCC}$ contains more than one query node of $Q$. TopK first verifies whether a candidate matches the nontrivial node. It then employs a fixedpoint strategy to propagate relevance changes: when a candidate $v$ is known to be a match of $u$, relevance changes caused by $v$ is propagated to the matches of those query nodes in $u_{SCC}$ only, to adjust their vectors. The propagation proceeds until a fixpoint is reached, i.e., when no vector can be updated in the propagation for all the candidates of the query nodes in this $u_{SCC}$.

**Algorithm.** Similar to TopKDAG, TopK works in two steps, i.e., initialization and propagation. In the initialization step, (a) it defines the rank $r(u)$ of a query node $u$ of $Q$ to be the rank $r(u_{SCC})$ of the node $u_{SCC}$ in $Q_{SCC}$, and (b) for each candidate $v \in \text{can}(u)$ with $r(u) = 0$, if $u_{SCC}$ contains a single node $u$, it assigns a vector $v.T = (X_v = \text{true}, \emptyset, 0, 0)$ to $v$; otherwise, $v.T$ is initialized in the same way as in TopKDAG.

In the propagation step, TopK selects a set $S_c$ of candidates, such that for each node $v$ in $S_c$, there exist an SCC node $u_{SCC}$ ranked 0 in $Q_{SCC}$ and a query node $u \in u_{SCC}$, where $u$ and $v$ have the same label. For each candidate $v \in \text{can}(u)$ of a query node $u \in u_{SCC}$, it first verifies whether

---

**Procedure SccProcess**

**Input:** pattern $Q = (Q_P, E_P, f_r, u_v)$, graph $G = (V, E, L)$, node $v$, a nontrivial node $u_{SCC} \in Q_{SCC}$, and a min-heap $S$.

**Output:** Updated $(G, S)$.

1. **stack $V_A := \emptyset$; termination := false**;
2. **push $v$ onto $V_A$**;
3. **while $V_A \neq \emptyset$ and termination := false do**
4. **node $v := V_A.pop()$; $X_v :=$ true**;
5. **for each $(v', v) \in E$ and $(u', u) \in E_P$ do**
6. **update $v.T$**;
7. **if $X_{v'}$ is evaluated to true then**
8. **if $v' \neq v$ then $V_A.push(v')$**;
9. **else if $v' = v$ then**
10. **update $v.T$ for each $v \in V_A$**;
11. **if $u' = u_v$ then update $S$**;
12. **check the termination condition; update termination;**
13. **if termination == true then break**;
14. **if $v$ is a nontrivial node then restore $v'.bf$ for each visited node $v'$**;
15. **return $(G, S)$**;

---

**Figure 3: Procedure SccProcess**

$v$ matches $u$ via procedure SccProcess, when $u_{SCC}$ contains more than one query node. After validity checking of $v$, if $v.bf$ is evaluated true, i.e., $v$ has children as matches of each child of $u$, TopK then propagates relevance as follows: (a) if $u_{SCC}$ contains $u$ only, the propagation process from $v$ is the same as in procedure AcyclicProp (Section 4.1); (b) otherwise, it employs the similar strategy as procedure SccProcess (which takes $v$ as an “entry” node $v$ in its input) and propagates relevance to matches of nodes in $u_{SCC}$ only.

**Procedure SccProcess.** The procedure is given in Fig. 3. It takes among the input a candidate $v$ as an “entry” node. It uses a stack $V_A$ to perform propagation, and a Boolean variable termination to indicate termination (line 1-2). Utilizing $V_A$, it performs a reversed depth-first traversal of $G$ starting from $v$ at the top of $V_A$ (lines 3-13). For each $v' \in \text{can}(u')$ encountered (line 5), where $u'$ is a query node, SccProcess updates $v'.T$ in the same way as in TopKDAG (line 6). If $v'.bf$ can be evaluated to be true (line 7), (1) if $v'$ is not $v$, $v'$ is pushed onto the stack to continue the reversed depth-first traversal (line 8), (2) otherwise (line 9), one can verify that all the nodes in stack $V_A$ are valid matches, since they correspond to query nodes in $u_{SCC}$. Hence for each $v \in V_A$, it updates $v.T$ by letting $v.R := v.R \cup V_A$ and $v.I := |v.R|$ (line 10). Furthermore, if $u'$ is the output node, it updates $S$ with new matches (line 11), checks the termination condition (Proposition 3), and terminates if the condition holds (lines 12-13).

If $v.bf$ is still false after the while loop, $v$ is not a match. Thus for each node $v'$ visited in the loop, $v'.bf$ is restored to its original form saved earlier (line 14). SccProcess returns the updated vectors and $S$ for further propagation (line 15).

**Example 8:** Recall graph $G$ and pattern $Q$ from Fig. 1. TopK finds top-2 matches for $PM$ as follows. It first computes $Q_{SCC}$ of $Q$, which has a nontrivial node $DB_{SCC}$ containing DB and PRG. It starts with $Q_{SCC}$, a set of candidates $S_c := \{ST_3, ST_4\}$. When the propagation reaches candidates of $DB_{SCC}$ (parts of) their vectors are shown as below.

<table>
<thead>
<tr>
<th>$v$</th>
<th>$v.T$</th>
<th>$v.bf$</th>
<th>$v.m$</th>
<th>$v.c$</th>
<th>$v.R$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$DB_2$</td>
<td>$(X_{DB_2} = X_{DB_2, true \emptyset, 0, 0})$</td>
<td>$\emptyset$</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>$PRG_2$</td>
<td>$(X_{PRG_2} = X_{PRG_2, true \emptyset, 0, 0})$</td>
<td>$\emptyset$</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>$DB_3$</td>
<td>$(X_{DB_3} = X_{DB_3, true \emptyset, 0, 0})$</td>
<td>$\emptyset$</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>$PRG_3$</td>
<td>$(X_{PRG_3} = X_{PRG_3, true \emptyset, 0, 0})$</td>
<td>$\emptyset$</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>$DB_{PRG}$</td>
<td>$(X_{DB_{PRG}} = X_{DB_{PRG}, true \emptyset, 0, 0})$</td>
<td>$\emptyset$</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
TopK then invokes SCCProcess to check the validity of those candidates for the query nodes in $DB_{SCC}$. Assume that $SCCProcess$ first pushes $DB_3$ onto stack $V_A$ (line 2). It then propagates $X_{DB_3} = \text{true}$ upwards, updates $PRG_2.bf$ to $X_{PRG_2} = \text{true}$ and pushes $PRG_2$ onto $V_A$. Similarly, $DB_2.bf$ and $PRG_3.bf$ are updated to $X_{PRG_3} = \text{true}$ and $X_{PRG_3} = \text{true}$ successively. When $DB_2$ is encountered, $SCCProcess$ updates $DB_2.T$ to $\langle X_{PM} = \text{true}, \{ST_1, ST_4, DB_2, PRG_2, PRG_3\}, 6, 6 \rangle$. It then updates vector for each node in $V_A$ (line 10). After this, the vectors of the candidates for PMs are as follows ($i \in \{3, 4\}$):

<table>
<thead>
<tr>
<th>v</th>
<th>X_{PM} = \text{true}, {ST_1, ST_4, DB_2, PRG_2, PRG_3}, 6, 6</th>
</tr>
</thead>
<tbody>
<tr>
<td>PM_1</td>
<td>$X_{PM_1} = \text{true}, {ST_1, DB_3, PRG_2, PM_2}, 6, 6$</td>
</tr>
<tr>
<td>PM_2</td>
<td>$X_{PM_2} = \text{true}, {ST_1, ST_4, DB_2, PRG_2, PRG_3}, 6, 6$</td>
</tr>
</tbody>
</table>

Observe that after a single propagation, the termination condition in Proposition 3 is satisfied: $PM_l.l = PM_l.l = 6$, which are no less than $PM_1.h, i.e., 4$ and $PM_2.h$. Thus TopK returns $PM_2$ and $PM_3$ as top-2 matches.

Correctness & Complexity. SCCProcess always reaches a fixpoint, at which it correctly finds matches of the query nodes in SCC nodes. Indeed, (a) $SCCProcess$ stops when either the termination condition is true (line 12), or $X_v$ is updated to $\text{true}$ (and never changed back to false) for all the (finite many) candidates $v$ of $u$ in $SCC_0$ (lines 7, 14); and (b) $SCCProcess$ changes $X_v$ to $\text{true}$ if $v$ is a match. The correctness of propagation and termination condition for TopK can be verified along the same lines as for TopKDAG. For the complexity, the initialization is in $O(|Q|(|G|))$ time, and propagation is in $O(|V||(|V|+|E|))$ time. Thus TopK is in $O(|Q|(|G|+|V||(|V|+|E|)))$ time. Moreover, along the same lines as for TopKDAG, one can verify that TopK has the early termination property, by Proposition 3.

From the analysis above Proposition 2 follows.

Generalized top-$k$ matching. The result below shows that our techniques can be readily applied to generalized relevance functions given in Section 3 (see [1] for a proof).

Proposition 4: TopKDAG and TopK can be extended for generalized topK, with the early termination property.

The techniques can be easily extended to patterns with multiple output nodes that are not necessarily “roots” [1].

5. FINDING DIVERSIFIED MATCHES

In this section, we investigate the diversified top-$k$ matching problem (topKDP). In contrast to topK that is based on $\delta_0$ alone, the topKDP problem is intractable. The main result of this section is as follows.

Theorem 5: The topKDP problem is (1) NP-complete (decision problem); (2) 2-approximable in $O(|Q|(|G|+|V||(|V|+|E|)))$ time, and (3) has a heuristic in $O(|Q|(|G|+|V||(|V|+|E|)))$ time, but with the early termination property.

We prove Theorem 5(1) as follows. The decision problem of topKDP is in NP, since one can guess a $k$-element set $S$ and then check whether $S \subseteq M_0(Q, G, u_o)$ and $F(S) \geq \beta$ in $\text{PTIME}$. To show the lower bound, observe that by setting $\lambda = 1$, topKDP includes the $K$-diverse set problem [35] as its special case, which is known to be NP-hard [35]; hence topKDP is NP-hard. Thus, topKDP is NP-complete.

Recent results for the max-sum diversification [4] suggests that topKDP is, in general, nontrivial to approximate. Given a set $U$ with a distance function $\delta_0$ over the elements in $U$, the problem is to find a $k$-element subset $S$, which maximizes $F_k(S) = f(S) + \frac{1}{c} \sum_{u \in S} \delta_0(u, v)$, where $f(S)$ is a submodular function (see Section 3). Our diversification function $F'(\cdot)$ is in the form of $F_k(S)$, if normalized by $(1-\lambda)$. It is shown in [4] that no polynomial time algorithm can approximate $F_k(\cdot)$ within $\frac{|S|}{\lambda}$, assuming $P \neq \text{NP}$. In addition, it is shown that the diversification problem for submodular functions is approximable within $(1-\varepsilon)$ [17]. However, $F'(\cdot)$ is not submodular, as remarked earlier in Section 3.

Despite the hardness, we provide two algorithms for topKDP. (1) One is an approximation algorithm to compute diversified matches with approximation ratio 2, hence proving Theorem 5(2) (Section 5.1). (2) The approximation algorithm may be costly on large graphs, however. Thus we give a heuristic algorithm for topKDP with the early termination property (Section 5.2), verifying Theorem 5(3).

5.1 Approximating Diversification

We show Theorem 5 (2) by presenting an approximation algorithm, denoted by TopKDiv. In a nutshell, TopKDiv iteratively chooses a pair of matches that “maximally” introduces diversity and relevance to the selected matches, following a greedy strategy. This is done by (1) “rounding down” the diversification function $F'$ with a revised $F'$, and (2) finding a solution that maximizes $F'$, which in turn guarantees an approximation ratio for $F'$. This technique is commonly used for optimization problems [13, 34].

Algorithm. Given $Q$, $G$, and an integer $k$, algorithm TopKDiv identifies a set $S'$ of $k$ matches of $u_o$, such that $F(S') \geq \frac{\lambda}{\lambda-1}$, where $S'$ is an optimal set of $k$ matches that maximizes $F'$. That is, TopKDiv approximates topKDP with approximation ratio 2.

TopKDiv first initializes a min-heaps $S$ for top-$k$ matches, and an integer counter $i$. It then computes $M(Q, G, \lambda)$, the relevance $\delta_i(u_o, v)$ and diversity $\delta(v', v', v)$ for all matches $v, v' \in M_0(Q, G, u_o)$. Next, it iteratively selects two matches $(v_1, v_2)$ that maximize $F'(v_1, v_2) = \frac{1}{\lambda} \cdot \delta_i(u_o, v_1) + \delta_j(u_o, v_2)) + \frac{1}{\lambda} \cdot \delta_i(v_1, v_2)$; it then adds (resp. removes) them to $S$ (resp. from $M_0(Q, G, u_o)$). This process repeats $\frac{1}{\lambda}$ times. If $k$ is odd, $|S| = k - 1$; TopKDiv then greedily selects a match $v$ to maximize $F(S \cup \{v\})$. Finally, it returns $S$ We present the details of TopKDiv in [1].

Example 9: Given graph $G$ and pattern $Q$ of Fig. 1, and assuming $\lambda = 0.5$, TopKDiv finds top-2 diversified matches for PM as follows. (1) It first computes $M_0(Q, G, u_o) = \{PM_i | i \in \{1, 4\}\}$, and the relevance and diversity of those PM nodes (lines 1-2). (2) It then greedily selects a pair $(v_1, v_2)$ of matches that maximizes $F'(v_1, v_2) = 0.5\cdot \delta_i(u_o, v_1) + \delta_j(u_o, v_2)) + \delta_i(v_1, v_2)$ (lines 3-9). Then $\{PM_1, PM_3\}$ is selected, since $F'(PM_1, PM_3) = 1.45$ is maximum. Thus TopKDiv returns this pair. When $\lambda = 0.5$, this pair is a top-2 match based on $F(\cdot)$ (see Example 6).

Correctness & Complexity. TopKDiv returns $S$, which consists of $k$ matches for $u_o$ if $u_o$ has at least $k$ matches, and all matches of $u_o$ otherwise. We next show that TopKDiv approximates topKDP with ratio 2. To see this, note that an instance of TopKDiv can be transformed to an instance of the Maximum Dispersion problem (MAXDISP) [16]. The problem MAXDISP is to find a subgraph for a submodular induced by a $k$-node set $v$ from a weighted complete graph $G$, with
the maximum sum of node and edge weights. Given a
match set $M_u(Q, G, u_o)$, we construct a complete graph
$G_u$ in which each node (simply denoted as $v$) represents a
match $v \in M_u(Q, G, u_o)$ with a weight $\delta(v, u_v)$, and each
edge $(v_1, v_2)$ carries a weight $\delta(v_1, v_2)$. Given a set of $k$
matches $S \subseteq M_u(Q, G, u_o)$ and the corresponding $k$
node set $V_k$ in $G_u$, we define cost $F'(V_k) = \sum_{v_j, v_j \in S, j < k} F'(v_j, v_j)$, where $F'(v_j, v_j)$ is given in TopKDiv (line 4). One may verify that $F'(V_k) = (k - 1) \cdot \frac{1}{2} \sum_{i \in S} \delta_i(u_v, v_i) + \frac{2}{\lambda} \sum_{i, j \in S, i < j} \delta_{ij}(v_j, v_j) = F(S)$, where $F'$ is the
diversification function (Section 3). Thus, $S$ contains top-$k$ matches if
and only if $V_k$ maximizes $F'(V_k)$. Note that TopKDiv simu-
lates a greedy 2-approximation function for MAXDASP [16].
Hence, it returns a set $S$ of $k$ matches such that $F(S) \geq \frac{1}{2} \cdot F(S')$, where $S'$ refers to the optimal top-$k$ matches, i.e., TopKDiv approximates topKDP with ratio 2.

For the complexity, it takes $O(\lvert Q \rvert + \lvert V \rvert (\lvert V \rvert + \lvert E \rvert))$ time to compute $M_u(Q, G, u_o)$, and the relevance and distance values (line 1). It takes in total $O(\frac{1}{2} \lvert V \rvert^2)$ time to update $S$ with the greedy strategy (lines 3-9). Thus, TopKDiv is in $O(\lvert Q \rvert \lvert G \rvert + \lvert V \rvert (\lvert V \rvert + \lvert E \rvert))$ time in the worst case, since $k$ is typically treated a small constant. Hence, despite the necessary computation for diversifying the ranks, TopKDiv does not incur substantially extra cost compared to the algo-
rithms for computing top-$k$ matches based on $\delta(\cdot)$ alone.

This analysis above completes the proof of Theorem 5(2).

5.2 Early Termination Heuristics

Algorithm TopKDiv requires all the matches in $M(Q, G)$ to be computed, which may not be efficient for large graphs. To rectify this we present a heuristic algorithm for topKDP, denoted as TopKDH, with the early termination property.

Algorithm. Similar to TopK (Section 4), TopKDH (not shown) uses a min-heap $S$ to maintain top-$k$ matches; and initializes the same vector for each candidate. It updates the vectors via propagation to check the termination condi-
tion (Proposition 3). In contrast to TopK, TopKDH utilizes a greedy strategy to choose matches for $u_v$. In each propagation, it collects a set $S'$ of matches of $u_v$ with updated vectors. It then updates $S$ as follows: (a) if $\lvert S \rvert + \lvert S' \rvert \leq k$, $S = S \cup S'$; (b) otherwise, TopKDH iteratively replaces $v \in S$ with $v'$ to maximize $F'(S \setminus \{v\} \cup \{v'\}) - F'(S)$; here $F'$ rec-
ives $F(\cdot)$ by replacing $\delta_i(u_v, v)$ with $\lvert C_{uv(i)} \rvert$ and $\delta_{ij}(v_j, v_j)$ with $1 - \frac{x_{ij}}{\sqrt{V}}$; it then removes $v'$ from $S'$. Intuitively,
TopK DH always selects matches that “maximally” diversifies $S$. These steps repeat until $S'$ is $\emptyset$ or $\lvert S \rvert = k$.

Example 10: Consider graph $G$ and pattern Q from Fig. 1. Let $\lambda = 0.1$. TopKDH finds top-2 diversified matches for $PM$ as follows. It first selects $S = \{ST_3, ST_4\}$, and adjusts the vectors of the candidates. After the propagation, it selects $\{PM_3, PM_4\}$ as top-2 matches, which maximizes $F''(\cdot)$ as $0.9 + \frac{1}{2} + 0.2 + 1 = 1.1$. Now the condition of Proposition 3 is satisfied. Hence, TopKDH returns $\{PM_3, PM_4\}$, which is indeed a top-2 pair when $\lambda = 0.1$ (see Example 6).

Correctness & Complexity. Algorithm TopKDH differs from TopK only in that it does extra computation to select the
matches. One may verify its correctness along the same
lines as the argument for TopK given earlier. For the com-
plexity, the extra computation takes $O(|E|V^2)$ time in total. Thus TopKDH is still in $O(|Q|G) + |V||(|V| + |E|)\}$ time.

TopKDH terminates early: it processes as many matches as TopK does in propagation, and it stops as soon as the termination condition of Proposition 3 is satisfied.

The analysis completes the proof of Theorem 5(3).

Generalized diversified top-$k$ matching. Our diversified
matching algorithms can be easily extended for general-
ized diversified function $F''(\cdot)$ (Section 3.4), preserving the
nice properties, e.g., early termination and approximation ratio. We defer the detailed algorithms and proofs to [1].

Proposition 6: Algorithm TopKDH (resp. TopKDiv) can be extended for generalized topKDP, with the early termination property (resp. preserving approximation ratio 2).

6. EXPERIMENTAL EVALUATION

We next experimentally verify the effectiveness and ef-
fiency of our top-$k$ graph pattern matching algorithms, using real-life and synthetic data (see [1] for more results).

Experimental setting. We used the following datasets.

(1) Real-life graphs. We used three real-life graphs.
(a) Amazon (http://snap.stanford.edu/data/index.html) is a product co-purchasing network with 548,552
nodes and 1,788,725 edges. Each node has attributes such
as title, group and sales rank. An edge from product $x$ to $y$ indicates that people who buy $x$ also buy $y$.
(b) Citation (http://www.arnetminer.org/citation/) contains 1,397,240 nodes and 3,021,489 edges, in which
debug samples a portion of papers with attributes (e.g., title, authors, year and publication venue), and edges denote citations.
(c) YouTube (http://netseg.cs.sfu.ca/youtubedata/) is a
network with 1,609,969 nodes and 4,509,826 edges. Each
node is a video with attributes (e.g., (A)ge, (C)ategory, (V)iews, (R)ating). An edge $(x, y)$ indicates that the
publisher of video $x$ recommends a related video $y$.

(2) Synthetic data. We designed a generator to produce
synthetic graphs $G = (V, E, L)\}$, controlled by the number
of nodes $|V|$ and edges $|E|$, where $L$ are assigned from a
set of 15 labels. We generated synthetic graphs following the
linkage generation models [12]: an edge was attached to the
high degree nodes with higher probability (see [1] for
details). We use $(|V|, |E|)$ to denote the size of $G$.

(3) Pattern generator. We also implemented a generator for
graph patterns $Q = (V_p, E_p, f_p, u_{o})$, controlled by four pa-
rameters: $|V_p|$, $|E_p|$, label $f_p$ from the same $\Sigma$, and the
output node $u_o$. We denote as $(|V_p|, |E_p|)$ the size $|Q|$ of
$Q$. For synthetic graphs, we manually constructed a set of
9 patterns including 4 DAG patterns and 5 cyclic patterns.

For Amazon, we identified 10 cyclic patterns to search
products with conditions specified on attributes (e.g., title, category) and their connections with other products. Ci-
tation is a DAG, and we designed 14 DAG patterns to find
papers and authors in computer science. For Youtube, we
found 10 cyclic patterns, where each node carried search
conditions for finding videos, e.g., category is “music”.

Two such patterns on Youtube are shown in Figures 4(a) and
4(b). (a) The cyclic pattern $Q_1$ in Fig. 4(a) is to find
top-2 videos in category “music” (marked with “*” as the
output node) with rating $R > 2$ (out of 5), which are
related to “entertainment” videos with $R > 2$ and have been
watched more than 5000 times ($V > 5000$). (b) Similarly,
and Match Performance for cyclic patterns

(a) Pattern (I) and top-2 results on Youtube

(b) Pattern (II) and top-2 results on Youtube

Figure 4: Case study

the DAG pattern $Q_2$ in Fig. 4(b) is to identify top-2 “comedy” videos with recommendation requirements.

(4) Implementation. We implemented the following algorithms, all in Java: (1) our top-k algorithms TopKDAG for DAG patterns and TopK for cyclic patterns; (2) algorithm TopKopt (resp. TopKDAGopt), a naive version of TopK (resp. TopKDAG) that randomly selects $S_c$ to start propagation, rather than choosing a minimal set $S_c$ that covers those candidates of query nodes of rank 1 (see Section 4); (3) algorithm Match for top-k matching, to compare with TopKDAG and TopK; (4) the approximation algorithm TopKDiv and heuristic algorithms TopKDAGDH (resp. TopKDAGDHD) to find diversified top-k matches for general (resp. DAG) patterns.

All the experiments were repeated 5 times on a 64bit Linux Amazon EC2 Instance with 3.75 GB of memory and 2 EC2 Compute Unit, and the average is reported here.

Experimental results. We next present our findings.

Exp-1: Effectiveness of top-k matching. We first evaluated the effectiveness of our top-k matching algorithms, i.e., TopKDAG (resp. TopK) and its naive version TopKDAGopt (resp. TopKopt), compared to Match. We measured their effectiveness by (1) counting the number of the matches $|M_k(Q,G,u)|$ of $u$, inspected by them, and (2) computing a match ratio $MR = |M_k(Q,G,u)| / |M_k(Q,G,u)|$.

We compared MR of these algorithms over the three real life datasets: (1) TopK, TopKopt and Match on Youtube by varying $|Q|$ (Fig. 5(a)), (2) TopKDAG, TopKDAGopt and Match on Citation by varying $|Q|$ (Fig. 5(b)), and (3) TopK, TopKopt and Match on Amazon by varying $k$ (Fig. 5(c)). The algorithms performed consistently on different datasets, and hence we do not show all the results here. Moreover, (a) Match always finds all the matches, i.e., its MR is 1, and is thus not shown; and (b) Citation is a DAG, and thus only TopKDAG, TopKDAGopt and Match were tested on Citation for DAG patterns.

Performance for cyclic patterns. Fixing $k = 10$, we varied DAG pattern size $|Q|$ from (4, 6) to (10, 15) on Citation. As shown in Fig. 5(b), (1) TopKDAG inspects much less matches than Match. For example, its MR is only 34% when $|Q| = (8, 12)$, and is 40% on average. (2) On average, TopKDAG examined 18% less matches than TopKDAGopt. The reduction in MR is more evident for DAG patterns than for cyclic patterns because DAG patterns are less restrictive and hence, $M(Q,G)$ tends to be larger.

Varying $k$. Fixing pattern size $|Q| = (4, 8)$, we varied $k$ from 5 to 30 in 5 increments, and reported MR for TopK and TopKopt on Amazon. As shown in Fig. 5(c), the match ratio MR of TopK (resp. TopKopt) increased from 42% (resp. 46%) to 69% (resp. 77%) when $k$ was increased from 5 to 30. Indeed, when $k$ becomes larger, more matches have to be identified and examined, for both TopK and TopKopt.

Exp-2: Efficiency and scalability of top-k matching. We next evaluated the efficiency of the algorithms. In the same settings as in Exp-1, we report the performance of (1) TopK, TopKopt and Match on Youtube by varying $|Q|$ (Fig. 5(d)), (2) TopKDAG, TopKDAGopt and Match on Citation by varying $|Q|$ (Fig. 5(e)), and (3) TopK, TopKopt and Match on Amazon by varying $k$ (Fig. 5(f)). We also evaluated their scalability with synthetic data.

Efficiency for cyclic patterns. The results for cyclic patterns on Youtube are shown in Fig. 5(d), which are consistent with Fig. 5(a): (1) TopK and TopKopt always outperform Match; TopK (resp. TopKopt) takes 52% (resp. 64%) of the time of Match on average. (2) On average, TopK improves TopKopt by 18%. (3) While all the algorithms take more time for larger patterns, Match is more sensitive to $|Q|$ than TopK, because Match spends 98% of its time on computing all the matches and their relevance, which heavily depend on $|Q|$.

Efficiency for acyclic patterns. As shown in Fig. 5(e), the results for DAG patterns on Citation are consistent with Fig. 5(d). (1) TopKDAG (resp. TopKDAGopt) outperforms Match by 64% (resp. 56%) on average, and (2) TopKDAG improves TopKDAGopt by 16%. The improvement over Match is more evident for DAG patterns than for cyclic patterns (Fig. 5(d)) because (a) MR is smaller for DAG patterns, and (b) TopKDAG does not need fixpoint computation.

Varying $k$. On Amazon, Figure 5(f) reports the efficiency results in the same setting as in Fig. 5(c): (1) Match is insensitive to $k$, as it computes the entire $M_k(Q,G,u)$. (2) TopK and TopKopt outperform Match, but are sensitive to the change of $k$. Indeed, the benefit of early termination degrades when $k$ gets larger and more matches need to be identified. Nonetheless, $k$ is small in practice, and TopK is less sensitive than TopKopt, as its selection strategy allows early discovery of top matches, reducing the impact of $k$.

In addition, we found that TopK and TopKDAG perform better for patterns with (a) smaller “height” (i.e., the largest rank of the pattern node), (b) output nodes with smaller ranks, and (c) less candidates. We present the details in [1].
Scalability. We also evaluated the scalability of these algorithms using large synthetic datasets. Fixing $|Q| = (4, 6)$ for DAG patterns and $k = 10$, we varied $|G|$ from $(1M, 2M)$ to $(2.8M, 5.6M)$, and tested TopKDiv, TopKDAGopt and Match. As shown in Fig. 5(g), the results tell us the following: (a) TopKDAG and TopKDAGopt scale well with $|G|$, and better than Match; they account for only 38.1% and 43.2% of the running time of Match, respectively; and (b) TopKDAG takes 87% of the running time of TopKDAGopt. These are consistent with the results on real-life graphs.

Fixing $k = 10$, we used cyclic patterns with size $|Q| = (4, 8)$, and tested the scalability of TopK, TopKopt and Match. As shown in Fig. 5(h), the results are consistent with Fig. 5(g): TopK (resp. TopKopt) accounts for 49% (resp. 56%) of the cost of Match for cyclic patterns. A closer examination of the above results also tells us that our algorithms do much better than their worst-case complexity, due to early termination.

Exp-3: Diversified top-$k$ matching. Finally, we evaluated (1) the effectiveness of TopKDiv and TopKDH, (2) the efficiency of TopKDiv, TopKDH and TopKDAGDH, as well as (3) their scalability using large synthetic data.

Effectiveness. Observe that (a) the MR of TopKDiv is always 1, as it requires $M_{u}(Q, G, u_{o})$ to be computed, and (2) the MR of TopKDH (resp. TopKDAGDH) is the same as that of TopK (resp. TopKDAG), since they only differ in match selection strategy (see Section 5). Thus, the comparison of MR’s for TopKDiv, TopKDH and TopKDAGDH is consistent with the results in Figures 5(a) and 5(b). Instead, we are interested in how well TopKDH and TopKDAGDH, as heuristics, “approximate” the optimal diversified matches.

Fixing $\lambda = 0.5$ and $k = 10$, we tested $F(S)$ and $F(S')$ on Amazon by varying $|Q|$, where $S$ (resp. $S'$) is the set of top-$k$ diversified matches found by TopKDiv (resp. TopKDH), and $F(\cdot)$ is the diversification function given in Section 3. As shown in Fig. 5(i), (1) $F(S) \geq F(S')$, as expected since TopKDiv has approximation ratio 2, while TopKDH is a heuristic. (2) However, TopKDH is not bad: $F(S')$ is 77% of $F(S)$ in the worst case. Thus TopKDH, on average, “approximately” finds a set $S'$ with $F(S') \geq \frac{1}{2}$ of the optimal value, which is comparable to the performance of TopKDiv.

Case study. We also manually checked the top-2 diversified matches found by TopKDH for $Q_{1}$ and $Q_{2}$ of Figures 4(a) and 4(b), respectively. As also shown in Fig. 4, TopKDH correctly replaced one of the top-2 relevant matches with another (shadowed node) that made the match set diverse.

Efficiency. On Citation, we tested the efficiency of TopKDiv and TopKDAGDH, by fixing $k = 10$ and varying $|Q|$ from $(3, 2)$ to $(7, 6)$. As shown in Fig. 5(j), (1) TopKDAGDH takes only 42% of the time of TopKDiv on average, but (2) TopKDiv is less sensitive to $|Q|$ than TopKDAGDH, due to the tradeoff between the extra time incurred by larger $Q$ for TopKDiv to compute $M(Q, G)$ and the reduced time for selecting diversified matches from smaller $M(Q, G)$.

Fixing $k = 10$, we evaluated the efficiency of TopKDiv vs. TopKDH on Youtube by using the same patterns as for TopK in Exp-2 (Fig. 5(d)). Figure 5(k) shows the results, which are consistent with Fig. 5(j) for DAG patterns on Citation.

We also found that both algorithms are not sensitive to the change of $\lambda$. Specifically, TopKDiv takes slightly less time when $\lambda = 0$, as it degrades to Match (see [1] for details).

Scalability. We also evaluated the scalability of TopKDiv and TopKDH, in the same setting as in Fig. 5(h). As shown in Fig. 5(l), (1) both algorithms scale well with $|G|$, and (2) the running time of TopKDH is less sensitive than that of TopKDiv. Indeed, TopKDiv spends more time on computing $M(Q, G)$ for larger $G$, and its running time grows faster than that of TopKDH. TopKDH seldom demonstrates its worst case complexity, due to early termination.
Summary. (1) The revised graph pattern matching effectively reduces excessive matches: TopkDAG (resp. Topk, TopkDAG) only examines 40% (resp. 45%) of matches in $M(Q,G)$ on average. (2) Our early-termination algorithms outperform Match, which is based on traditional matching. Indeed, TopkDAG (resp. Topk) takes on average 36% (resp. 52%) of the time of Match for DAG (resp. cyclic) patterns. (3) Our algorithms effectively identify most relevant and diversified matches for output nodes, and scale well with $k$ and the sizes of $Q$ and $G$. (5) Our optimization technique improves the efficiency of the top-$k$ matching algorithms by 16% (resp. 18%) for DAG (resp. cyclic) patterns.

7. CONCLUSION

We have introduced and studied the (diversified) top-$k$ graph pattern matching problems. We have revised graph patterns by supporting a designated output node, and defined functions to measure match relevance and diversity, as well as a bi-criteria objective function based on both. We have established the complexity for these problems. In addition, we have provided algorithms for computing top-$k$ matches based on relevance alone, and for finding diversified top-$k$ matches, with properties such as constant approximation ratios and early termination. As verified analytically and experimentally, our methods indeed remedy the limitations of prior matching algorithms, by eliminating excessive matches and improving efficiency on big real-life social graphs. Better still, they can be employed to support a wide range of ranking functions commonly used in practice.

The work is a first step toward effective top-$k$ matching on big social data. We are currently experimenting with various real-life graphs, ranking functions, and patterns (with multiple output nodes [1]), to fine-tune our diversification objective function. We are also exploring optimization techniques to further reduce the number of matches examined by our algorithms. The ultimate goal is to make graph pattern matching feasible on big social data. To this end, we are developing distributed top-$k$ matching algorithms on graphs that are partitioned, distributed and possibly compressed.
