List of abbreviations: BMDC: bone marrow derived dendritic cell; cDC: conventional dendritic cell; pDC: plasmacytoid dendritic cell; Clec1b: C-type lectin domain family 1, member B; CLEC-2: C-type lectin-like receptor 2; DC: dendritic cell; FCS: foetal calf serum; FL: foetal liver; FRC: fibroblastic reticular cell; GeoMFI: geometric mean fluorescence intensity; MLN: mesenteric lymph node; PDPN: podoplanin; RANKL: receptor activator of NFκB ligand; SLO: secondary lymphoid organ.

Abstract

Expression of mouse CLEC-2 has been reported on circulating CD11b\textsuperscript{high} Gr1\textsuperscript{high} myeloid cells and dendritic cells (DCs) under basal conditions, as well as on a variety of leucocyte subsets following inflammatory stimuli or in vitro cell culture. However, previous studies assessing CLEC-2 expression failed to use CLEC-2-deficient mice as negative controls and instead relying heavily on single antibody clones. Here, we generated CLEC-2-deficient adult mice using two independent approaches and employed two anti-mouse CLEC-2 antibody clones to investigate surfacce expression on haematopoietic cells from peripheral blood and secondary lymphoid organs (SLOs). We rule out constitutive CLEC-2 expression on resting DCs and show that CLEC-2 is up-regulated in response to LPS-induced systemic inflammation in a small subset of activated DCs isolated from the mesenteric lymph nodes but not the spleen. Moreover, we demonstrate for the first time that peripheral blood B lymphocytes present exogenously derived CLEC-2 and suggest that both circulating B lymphocytes and CD11b\textsuperscript{high} Gr1\textsuperscript{high} myeloid cells lose CLEC-2 following entry into SLOs. These results have significant implications for our understanding of CLEC-2 physiological functions.
Introduction

Many physiological functions are critically regulated by fine-tuned interactions between diverse subsets of haematopoietic and non-haematopoietic cells within primary and secondary lymphoid organs as well as in the circulation. These interactions are mediated by surface receptors or secreted molecules that display complex cellular, spatial and temporal expression patterns. A deep understanding of these patterns is required for a full knowledge of their physiological significance and for effective therapeutic intervention. For example, expression of RANKL by bone osteoblasts regulates bone density while its expression by developing thymocytes regulates medullary thymic epithelial cell maturation (for review see [1]).

A similar scenario can be considered for the C-type lectin-like receptor CLEC-2 and its ligand podoplanin (PDPN), which are involved in a variety of physiological and pathophysiological processes (for review: [2]). While CLEC-2 expression is restricted to haematopoietic cells, PDPN is more ubiquitously expressed, with constitutive expression in the lungs [3], kidneys [4], brain [3], thymus [5], secondary lymphoid organs (SLOs) [6, 7], lymphatic vessels and bones [8]. PDPN expression is also up-regulated at the leading edge of tumours and in additional haematopoietic and non-haematopoietic cell-types during inflammation (for review: [2]). CLEC-2/PDPN interactions play essential roles in the immune system, as they prevent blood-lymph mixing [9-11], are required for lymph-node (LN) development [12] and maintenance of LN vascular integrity [12, 13] and contribute to the generation of optimal adaptive immune responses [12, 14, 15].

CLEC-2 surface expression on platelets was first demonstrated in humans [16] and soon after in mouse [17] and chicken [18]. The expression of CLEC-2 and its RNA transcript – encoded by the Clec1b gene – has also been studied in leucocytes isolated from different species leading to a rather confusing mosaic of results. While CLEC-2 is absent from chicken leucocytes [18] and restricted to liver-resident Küppfer cells in human [19-22], a much broader expression profile of CLEC-2/Clec1b has been reported in rodent leucocytes, particularly in mice.

While one report claims that mouse CLEC-2 surface expression by leucocytes is restricted to monocytes and liver-resident Küppfer cells [20], other studies using a different antibody clone (17D9), or the fusion protein PDPN-Fc, reported that CLEC-2 is
constitutively expressed by CD11b<sup>high</sup> Gr1<sup>high</sup> cells isolated from bone marrow and whole blood, splenic B lymphocytes, a small subset of splenic natural killer (NK) cells, splenic plasmacytoid dendritic cells (pDCs), splenic conventional DCs (cDCs), GM-CSF stimulated bone marrow derived DCs (BMDCs), Flt3L BMDC, as well as peripheral lymph node (LN) DCs [19, 23, 24]. With the exception of NKT cells and T lymphocytes, in vivo LPS challenge has been reported to up-regulate CLEC-2 expression in almost all splenic leucocyte subsets as well as peripheral LN DCs [23, 24]. In a thioglycolate-induced peritoneal inflammation model, CLEC-2 expression was observed in F4/80<sup>+</sup> macrophages but not in CD11b<sup>high</sup> Gr1<sup>high</sup> cells [19, 23]. Notably, CLEC-2-deficient negative control cells were not included in most of these studies [19, 23].

Our study aimed to clarify these contradictory findings and improve our understanding of CLEC-2 expression on mouse leucocytes. These results have important physiological consequences that will be discussed below.
Results and Discussion

Peripheral blood B lymphocytes and CD11b\textsuperscript{high} Gr-1\textsuperscript{high} cells present CLEC-2 on their surface

Previous studies that investigated the temporal, spatial and pro-inflammatory expression of CLEC-2 in the murine adult haematopoietic system have been hampered by the high neonatal mortality rate (>95%) of Clec1b\textsuperscript{-/-} mice [10, 20], impeding the inclusion of appropriate Clec1b\textsuperscript{-/-} negative control cells in previous studies aiming to define the temporal, spatial and post inflammatory expression of CLEC-2 in vivo [19, 23, 24].

To circumvent the neonatal mortality rate of Clec1b\textsuperscript{-/-} mice we developed a tamoxifen-inducible Clec1b deleting mouse line (Clec1b\textsuperscript{fl/fl}\times Rosa\textsuperscript{+/creERT2}). After 6 months on tamoxifen diet, peripheral blood leucocytes isolated from Clec1b\textsuperscript{fl/fl}\times Rosa\textsuperscript{+/creERT2} mice but not Clec1b\textsuperscript{fl/fl} littermate controls show genomic deletion of the Clec1b locus (Supporting Information Fig 1).

In parallel, we investigated CLEC-2 expression on haematopoietic cells isolated from lethally irradiated wild-type adult mice reconstituted with foetal liver (FL) cells from E14.5 Clec1b\textsuperscript{+/+} or Clec1b\textsuperscript{-/-} embryos [25]. This second experimental strategy was used to rule out potential side effects of tamoxifen on CLEC-2 expression. It is known that sex steroid hormones and their synthetic derivatives (such as tamoxifen) affect haematopoiesis due to the presence of oestrogen receptors on most immune cells [26, 27]. Moreover, tamoxifen has anti-inflammatory effects that could counteract LPS-mediated pro-inflammatory challenges [28-30]. In addition we used two different antibody clones, 17D9 [19, 23] and INU1 [31], reported to bind to mouse CLEC-2.

Initially, CLEC-2 expression was measured on circulating platelets, T lymphocytes, B lymphocytes and CD11b\textsuperscript{high} Gr-1\textsuperscript{high} cells from Clec1b\textsuperscript{0/0}\times Rosa\textsuperscript{+/creERT2} mice and Clec1b\textsuperscript{0/0} littermates by flow cytometry using the two antibody clones 17D9 and INU1 (Figure 1A and Supporting Information Figure 2). Following tamoxifen treatment, Clec1b\textsuperscript{0/0}\times Rosa\textsuperscript{+/creERT2} platelets showed full abrogation of CLEC-2 expression compared to Clec1b\textsuperscript{0/0} littermates.
using both 17D9 and INU1 (Figure 1A), confirming the efficiency of our inducible genetic mouse model.

On platelets, INU1 staining was found to be weaker than 17D9 staining in both control animals (Clec1b\(^{fl/fl}\) mice treated with tamoxifen and Clec1b\(^{fl/fl}\)xRosa26\(^{+/creERT2}\) mice fed normal diet). Furthermore, the geometric mean fluorescence intensity (GeoMFI) associated with 17D9 binding to leucocytes was on average 3-fold lower than that observed on platelets (Figure 1A), while INU1 discrimination power on leucocytes was too weak for detecting CLEC-2 on them (Figure 1A). As a result, we solely used the 17D9 clone to further investigate CLEC-2 expression on leucocytes.

In both the tamoxifen-inducible and radiation chimeric CLEC-2-deficient mouse models, the levels of 17D9 binding to circulating B lymphocytes were significantly reduced compared to controls (Figure 1A-B), suggesting that peripheral blood B lymphocytes constitutively express CLEC-2. Although CLEC-2 appeared to be down-regulated on circulating B lymphocytes following LPS treatment in chimeric mice, this was not statistically significant (Figure 1B), indicating that activated Clec1b\(^{+/+}\) B lymphocytes remain positive for CLEC-2 when compared to their activated Clec1b\(^{-/-}\) B cell counterparts.

In the absence of LPS-induced inflammation, CD11b\(^{high}\) Gr-1\(^{high}\) cells (which includes a mix of monocytes, granulocytes/neutrophils and a small subset of NK cells [32, 33]) isolated from Clec1b\(^{-/-}\) reconstituted animals were negative for CLEC-2 compared to Clec1b\(^{+/+}\) littermates (Figure 1B). This demonstrates that circulating CD11b\(^{high}\) Gr-1\(^{high}\) cells constitutively express CLEC-2 in line with previous reports [19, 23]. However, treatment with tamoxifen led to the loss of specific CLEC-2 staining since no significant difference was observed between Clec1b\(^{fl/fl}\)xRosa26\(^{+/creERT2}\) mice and their controls (Figure 1A). Tamoxifen is known to inhibit B lymphocyte and DC maturation by altering the surface membrane expression of molecules such as CD22 on B lymphocytes or MHC-II and CD86 on BMDC [34, 35]. Additional uncharacterized phenotypic changes leading to the appearance of new CLEC-2-independent binding sites might explain the non-specific binding of 17D9 to Clec1b\(^{fl/fl}\)xRosa26\(^{+/creERT2}\) B lymphocytes and CD11b\(^{high}\) Gr-1\(^{high}\) cells as the wild-type Clec1b DNA was undetectable in these cells (Figure 1A, Supporting Information Figure 1).
Similarly, after LPS challenge, 17D9 acquired the ability to bind to $Clec1b^{-/-}$ CD11b$^{\text{high}}$ Gr-1$^{\text{high}}$ cells leading to a 3.7 fold higher GeoMFI than in equivalent unstimulated cells (Figure 1B). This suggests that 17D9 binds to CD11b$^{\text{high}}$ Gr-1$^{\text{high}}$ cells in a CLEC-2-independent manner following LPS-activation. In T lymphocytes there was no evidence for 17D9 binding in any of our experimental conditions (Supporting Information Figure 3).

From these findings we suggest that mouse peripheral blood B lymphocytes and CD11b$^{\text{high}}$ Gr-1$^{\text{high}}$ cells present CLEC-2 on their surface at a much lower level than platelets. These data contrast with the lack of evidence for CLEC-2 expression in peripheral blood leucocytes in chickens or humans [18, 21] and with the absence of significant $Clec1b$ transcripts in human leucocyte subsets according to microarray analyses on the BioGPS database [21, 36]. This indicates that, while CLEC-2 expression by platelets is conserved through species, the presence of CLEC-2 in B lymphocytes and CD11b$^{\text{high}}$ Gr-1$^{\text{high}}$ cells is specific to mice. Whether the presence of CLEC-2 on these cells provides any particular features to the mouse immunological system remains unknown. Our data add to previous reports establishing important differences between the mouse and human immune systems [37].

**Most SLO-resident leucocytes do not express CLEC-2/$Clec1b$ at steady-state**

At steady-state, we observed comparable 17D9 binding to spleen and mesenteric lymph node (MLN) B lymphocytes, CD11b$^{\text{high}}$ Gr-1$^{\text{high}}$ cells, plasmacytoid DCs (pDCs), CD11b$^{\text{neg/int}}$ conventional DCs (CD11b$^{\text{neg/int}}$ cDCs) and CD11b$^{\text{high}}$ conventional DCs (CD11b$^{\text{high}}$ cDCs) isolated from $Clec1b^{-/-}$ radiation chimeras or their wild-type counterparts (Figure 2, Supporting Information Figure 4 and Supporting Information Figure 5). These results, that demonstrate a lack of CLEC-2 expression on these leucocytes, contradict previous observations made using the 17D9 antibody clone and PDPN-Fc recombinant protein that suggested that mouse CLEC-2 was constitutively expressed on all these cell types in spleen and on peripheral LNs’ cDCs [23, 24]. Moreover, we could not detect significant $Clec1b$ transcript levels in most of the leucocyte populations isolated from the spleen and the MLN (Figure 2E). The absence of $Clec1b$ transcripts in most resting leucocytes is supported
by two independent micro-array analyses performed by the ImmGen [38] and BioGPS [36] consortia (Supporting Information Figure 6).

Interestingly, in agreement with the ImmGen database, we did observe that CD11b\textsuperscript{int} F4/80\textsuperscript{pos} red pulp splenic macrophages express high levels of \textit{Clec1b} transcripts (Figure 2E). However, we were unable to detect surface CLEC-2 on the surface of these cells when comparing our foetal liver reconstituted animals (data not shown). Given that F4/80\textsuperscript{pos} red pulp splenic macrophages, which express PDPN, play a key physiological role in the clearance of senescent blood erythrocytes and platelets by phagocytosis [6, 39, 40], the \textit{Clec1b} transcripts detected in these cells are likely to derive from engulfed platelets.

These results suggest that CLEC-2 surface expression by peripheral blood B lymphocytes and CD11b\textsuperscript{high} Gr-1\textsuperscript{high} cells (Figure 1) is lost upon entry into SLOs (Figure 2). The majority of mouse B lymphocytes and pre-cDC monocytes migrating from peripheral blood toward lymph nodes enter via high endothelial venules (HEV), arriving in the T-cell zone which is rich in PDPN\textsuperscript{pos} fibroblastic reticular cells (FRC) [41]. Down-regulation or shedding of CLEC-2 by B-lymphocytes and CD11b\textsuperscript{high} Gr-1\textsuperscript{high} cells during their entry through the HEV might represent a functional mechanism to prevent inappropriate activation of PDPN\textsuperscript{pos} FRCs in the absence of infection. In this context, recent studies demonstrated that close interactions between antigen-activated CLEC-2\textsuperscript{pos} DCs and LN PDPN\textsuperscript{pos} FRCs are required for mounting an effective immune response by favouring DC recruitment, FRC activation and LN swelling [14, 15, 24].

**Most SLO-resident leucocytes remain CLEC-2-negative following LPS stimulation**

CLEC-2 was not up-regulated on splenic and MLN resident B lymphocytes, CD11b\textsuperscript{high} Gr-1\textsuperscript{high} cells, pDCs or CD11b\textsuperscript{neg/int} cDCs in response to intraperitoneal LPS challenge of \textit{Clec1b}−/− and \textit{Clec1b}+/+ reconstituted animals (Figure 2A, B, C and Supporting Information Figure 5). It has been shown that B lymphocyte stimulation via LPS/TLR4 favours their emigration from the blood into SLOs [42]. Interestingly, we could not observe any CLEC-2\textsuperscript{pos} B lymphocytes in the SLOs of LPS-stimulated mice (Figure 2), supporting the
observation that circulating activated B lymphocytes down-regulate CLEC-2 before entering into SLOs (Figure 1B). Kerrigan and collaborators have suggested the same CLEC-2 down-regulation process by circulating CD11b<sup>high</sup> Gr-1<sup>high</sup> cells upon reaching inflammatory sites [19]. As entry to both SLOs and inflammatory sites requires leucocyte rolling, arrest and transendothelial migration [41], it is tempting to suggest that CLEC-2 down-regulation or shedding by these leucocytes facilitates the completion of this three-step mechanism. Indeed, it has been shown that the shedding of transmembrane molecules is essential for these leucocytes transendothelial migrations [43-46]. We hypothesize that CLEC-2 could be lost via the same mechanisms.

CD11b<sup>high</sup> Gr-1<sup>high</sup> cells, pDCs and CD11b<sup>neg/int</sup> cDCs isolated from LPS-stimulated Clec1b<sup>−/−</sup> mice exhibited a higher level of 17D9 binding than Clec1b<sup>−/−</sup> non-challenged counterparts. Once again, these results indicate that the 17D9 antibody clone has the capacity to bind LPS-stimulated leucocytes in a CLEC-2-independent manner. The lack of Clec1b transcript up-regulation in LPS-stimulated leucocytes (Figure 2E) provides further evidence to support this conclusion and challenges previously described LPS-induced CLEC-2 up-regulation by most splenic resident leucocytes and peripheral LN cDCs [23, 24].

MLN but not splenic CD11b<sup>high</sup> cDCs acquire CLEC-2 following LPS stimulation

In agreement with the results detailed above, CLEC-2 expression was not detected on splenic CD11b<sup>high</sup> cDCs. However a modest but significant increase in staining of MLN-derived Clec1b<sup>+/−</sup> CD11b<sup>high</sup> cDCs compared to Clec1b<sup>−/−</sup> controls was observed after LPS injection (Figure 2D), indicating that LPS-stimulated MLN CD11b<sup>high</sup> cDCs have the capacity to up-regulate CLEC-2 (Figure 2D). However, we could not correlate the appearance of CLEC-2 on the membrane with a higher relative amount of Clec1b transcripts in the stimulated CD11b<sup>high</sup> cDCs (Figure 2E), suggesting that LPS stimulation regulates CLEC-2 expression in MLN CD11b<sup>high</sup> cDCs via post-transcriptional mechanisms.

Taken together, our results confirmed high levels of CLEC-2 expression on splenic platelets (data not shown), while no significant expression of CLEC-2 was observed on most
leucocyte populations investigated, both at steady-state and after LPS injection. However, we did observe an increase in CLEC-2 expression on activated CD11b\textsuperscript{high} cDCs isolated from the MLN. This increase was absent on splenic-activated cDCs.

The existence of cell-specific and tissue-specific regulation of CLEC-2 expression has previously been observed in the context of human rheumatoid arthritis, a chronic inflammatory disease where CLEC-2 expression was found to be restricted to tissue infiltrating platelets, while absent from activated DCs [22]. In contrast, FITC skin painting, FITC footpad immunization, or OVA/CFA subcutaneous injections in mice were found to contribute to the generation of an immune response that relies on CLEC-2 expression by activated DCs and their interaction with PDPN\textsuperscript{pos} lymphatic endothelial cells and PDPN\textsuperscript{pos} FRCs [14, 15, 24]. These studies demonstrate that CLEC-2 up-regulation is a characteristic of locally activated DCs migrating toward the draining lymph node [14, 15, 24] and not the systemic feature of an activated immune system [23]. In accordance with this, we only observed CLEC-2 up-regulation by activated DCs in the MLN, a SLO close to the LPS site of administration (i.e. the peritoneal cavity), but not in a remote SLO like the spleen. This suggests that the MLN CLEC-2\textsuperscript{pos} CD11b\textsuperscript{high} cDCs we observed may have recently migrated from the surrounding mesenteric tissue following LPS administration.

Normal lymphocyte homeostasis in B-cell Clec1b\textsuperscript{−/−} mice as B-cells do not produce CLEC-2

To gain insight into the potential physiological roles of CLEC-2 in B lymphocytes, we first visualised the lymph nodes from B lymphocyte-deficient Jh\textsuperscript{−/−} κ\textsuperscript{−/−} mice and saw no evidence of erythrocyte infiltration in the lymph nodes, similar to wild-type animals (Figure 3A), indicating that CLEC-2 on B lymphocytes does not play an important role in blood-lymph separation or the maintenance of HEVs.

In order to investigate if CLEC-2 on peripheral blood B lymphocytes contributes to lymphocyte homeostasis, we generated mice with a Clec1b\textsuperscript{−/−} deficiency restricted to the B cell lineage by mixing Clec1b\textsuperscript{−/−} foetal liver and Jh\textsuperscript{−/−} κ\textsuperscript{−/−} bone marrow cell suspensions (at a 1:9 ratio) that we injected in lethally irradiated C57BL/6 recipients (Supporting Information...
Figure 7A)[47]. The absolute numbers of lymphocytes in the blood, spleen and MLNs were monitored (Figure 3B and C, Supplementary Information Figure 7B and C). Both in the blood and the SLOs, the absolute numbers of B and T lymphocytes were normal. In the spleen, the numbers of follicular, non-follicular and marginal zone Clec1b−/− B lymphocytes were comparable to the controls. Contrary to the MLNs, a small increase in CD4+ T lymphocytes was observed in the spleen of Clec1b−/− animals. However, no-significant increase in naïve (CD62Lhi CD44int) or activated (CD44hi CD62L+) CD4+ T lymphocytes was noted in these animals. Similarly, the CD4+ T lymphocytes showed the same level of activation between Clec1b−/− and control animals. These results indicate that the deletion of Clec1b gene in the B cell lineage has no effect on lymphocyte homeostasis.

Despite the absence of a functional Clec1b gene, peripheral blood Clec1b−/− B lymphocytes were stained by 17D9 at the same level as Clec1b+/+ B lymphocytes (Figure 3D). In B lymphocyte Clec1b-deficient mice, 71% of the platelets were CLEC-2pos on average (Figure 3D), while the level of CLEC-2 expression by CD11bhigh Gr-1high cells was comparable to that found in controls (Supplementary Information Figure 7D). We compared the amount of Clec1b transcripts by quantitative PCR in B lymphocytes isolated from the peripheral blood, the MLNs and the spleen. In all 3 populations, the amount of Clec1b was extremely low and at a comparable level (Figure 3E). This last result corroborates a study on rat B lymphocytes showing that Clec1b transcripts are hardly detectable in these cells [48]. From these observations we conclude that peripheral blood B lymphocytes do not intrinsically express CLEC-2. Instead we propose that the CLEC-2 molecules detected on the surface of circulating B lymphocytes are derived from MHC-II antigen presentation, trogocytosis or exosomes/microparticles attached to the B cell membrane [49].
Concluding remarks

Our study confirms that CLEC-2 is constitutively expressed by mouse platelets and circulating CD11b\textsuperscript{high} Gr1\textsuperscript{high} myeloid cells and shows for the first time that CLEC-2 is present on the surface of peripheral blood B lymphocytes. These B cells do not produce CLEC-2 but likely acquire CLEC-2 molecules from other yet uncharacterised cell types. Our data suggest that both circulating B lymphocytes and CD11b\textsuperscript{high} Gr1\textsuperscript{high} myeloid cells lose CLEC-2 when entering SLOs. This loss of CLEC-2 might depend on the same mechanisms that are selectively shedding CD23 and CD62L from leucocytes during the transendothelial migration [43, 45, 46]. As CLEC-2 stimulates PDPN\textsuperscript{pos} FRCs in SLOs in order to mount a proper immune response [14, 15, 24], we propose that the loss of CLEC-2 by naïve B lymphocytes and CD11b\textsuperscript{high} Gr1\textsuperscript{high} myeloid cells entering in the SLOs might be a prerequisite to prevent untimely FRCs activation in absence of antigenic challenge.

The use of animals reconstituted with Clec1b\textsuperscript{-/-} FL and the measurements of Clec1b transcripts allowed us to rule out any constitutive CLEC-2 expression by most of the leucocyte subpopulations isolated from SLOs. We also demonstrated that isotype controls are not adequate when working with the 17D9 antibody clone. Finally we showed that LPS peritoneal injection induces CLEC-2 acquisition to the unique MLN activated DCs leucocyte population. Taken together with other studies our findings emphasize the notion that the expression of CLEC-2 is not only restricted to specific subsets of resting leucocytes and platelets but is determined both by the activation state and the anatomical site where immune responses take place.
Materials and Methods:

Mice and diets

Clec1b<sup>+/+</sup> [25], Clec1b<sup>fl/fl</sup> [25], Rosa26<sup>+/ERT2cre</sup> (Jackson Laboratory, ME) [50], Clec1b<sup>fl/fl</sup> x Rosa26<sup>+/ERT2cre</sup>, Jh<sup>−/−</sup>κ<sup>−/−</sup> [51, 52] and BoyJ mice were maintained in the Biomedical Services Unit, University of Birmingham. C57BL/6 mice were purchased from Harlan, UK. Animals were fed with FormulaLab Diet 5008 (LabDiet, St-Louis, MO). When required, 6-8 week old Clec1b<sup>fl/fl</sup> x Rosa26<sup>+/ERT2cre</sup> and their Clec1b<sup>fl/fl</sup> x Rosa26<sup>+/+</sup> control littermates were continuously fed with tamoxifen-supplemented diet TAM 400 (Harlan, UK). For isolation of embryonic foetal liver, the morning of vaginal plug detection was designated day 0.5 of gestation. Animal experiments were performed in accordance with UK Home Office legislation.

Mouse haematopoietic system reconstitution

C57BL/6 or BoyJ mice (8-10 weeks old) were given Baytril in the drinking water for 7 days prior to irradiations with two doses of 450rad, 3 hours apart. One hour after the last irradiation Clec1b<sup>+/+</sup> or Clec1b<sup>−/−</sup> E14.5 foetal liver cells were injected intravenously. For the generation of B-cell Clec1b deficient recipients, 2x10<sup>5</sup> Clec1b<sup>+/+</sup> or Clec1b<sup>−/−</sup> E14.5 foetal liver cells were mixed with 18x10<sup>5</sup> Jh<sup>−/−</sup>κ<sup>−/−</sup> bone marrow cells. Mice were left for 6-8 weeks post-injection before analysis or further challenged by intraperitoneal injection of 25μg of LPS (Chondrex) diluted in PBS or PBS only. Mice were analysed 16-18 hours post LPS or PBS injection. Successful LPS injections were confirmed by ≥5% weight loss over this period.

Tissue sampling and preparation

In all cases, cell centrifugation was performed at the average force of 275g for 4 min. Blood was sampled from the tail vein of Clec1b<sup>fl/fl</sup>, Rosa26<sup>+/ERT2cre</sup>; or Clec1b<sup>fl/fl</sup> x Rosa26<sup>+/ERT2cre</sup> mice into 20mM EDTA/PBS 1x solution. After centrifugation the supernatant was removed and the pellet resuspended in red blood cell lysis buffer (Sigma-Aldrich) at
room temperature for 5 minutes. Samples were centrifuged and resuspended in cold PBS 1x, 2% foetal calf serum (FCS), 2mM EDTA solution and stained for flow cytometry analysis or processed for genomic DNA extraction.

Whole blood from foetal liver reconstituted animals was drawn into acid citrate dextrose solution (9:1 volume) from the inferior vena cava under isofluorane anaesthesia and mixed to 20mM EDTA/PBS 1x solution. An aliquot of blood was centrifuged and processed as described above.

The spleen and the MLN were harvested into cold 2% FCS RPMI solution (Sigma-Aldrich). For cell sorting of T-cells, B-cells and NK cells, part of the spleen was mechanically dissociated on a 100mm mesh (Greiner Bio-one). In all the other cases, spleen or MLN were teased apart with dissection forceps in a 2% FCS RPMI solution containing 2.5 mg/mL of Collagenase D (Roche) and 2 mg/mL of DnaseI (Sigma-Aldrich). Cell suspensions were kept under magnetic stirring at 37°C for 45 min before centrifugation. Pellets were resuspended in a 2% FCS RPMI solution containing 2.5mg/mL of Collagenase/Dispase (Roche) and 2mg/mL of DnaseI (Sigma-Aldrich) and kept under magnetic stirring at 37°C for 30 min. Cell suspensions were adjusted to a final EDTA concentration of 5mM by the addition of a 0.5M EDTA solution and kept under magnetic stirring at 37°C for 5 min. Cell suspensions were centrifuged and the pellets resuspended in red blood cell lysis buffer (Sigma-Aldrich) as described above before processing for FACS staining.

**Antibodies, FACS analysis and cell sorting**

The full list of antibodies used is provided in Supporting Information Table 1. Anti-mouse CLEC-2-FITC 17D9 clone was mainly obtained from a commercial provider (AbD Serotec, 17D9) and compared to rat IgG2b-FITC (AbD Serotec, MCA1125FT). For some experiments, purified 17D9 (a kind gift from Caetano Reis e Sousa, Cancer Research UK, London) and purified rat IgG2b (R&D Systems) were used. Purified anti-mouse CLEC-2 INU1 clone (a kind gift from Bernhard Nieswandt, University of Würzburg, Germany) was used in conjunction with purified rat IgG1k (Biolegend, 400402). All purified antibodies were conjugated to AlexaFluor®488 using a monoclonal antibody labeling kit (Invitrogen).

Cells were stained with antibodies at 4°C in the dark in PBS 1x, 2 % FCS, 2 mM EDTA solution. Cells were washed and centrifuged twice before being resuspended in a cold
a PBS 1x, 2 % FCS, 2 mM EDTA, 1mg/mL DAPI solution. Flow cytometry acquisitions were performed on a 3 laser (405 nm, 488 nm, 633 nm) Cyan (Beckman Coulter) using Summit v4.3 software (Beckman Coulter). Flow cytometry cell sorting were performed on a MoFlo high-speed cell sorter and Astrios cell sorter (Beckman Coulter) using Summit software (Beckman Coulter). FACS data were analysed with FlowJo software 8.7 (Tristar).

**Quantitative PCR**

Total bone marrow was flushed with 2% FCS RPMI from the tibia and femur of both hind legs. A tenth of the cell suspension was centrifuged, the supernatant was removed and pellets were snap frozen on dry ice. Flow cytometry cell sorted cells were collected in PBS 1x, 2% FCS, 2mM EDTA solution, centrifuged, pelleted, snap frozen on dry ice and stored at -80°C.

mRNA was extracted using a ‘RNeasy Microkit’ (Qiagen) following the manufacturers instructions. cDNA was generated using the ‘High Capacity Reverse Transcription’ kit and random primers mix (Applied Biosystems). RT-PCR reaction settings were: 25°C, 10min; 37°C, 120min; 85°C, 10min. The cDNA obtained was diluted 1/2 with RNase-free/DNase-free water (Qiagen), pre-amplified using the ‘TaqMan Pre-Amp Master Mix’ kit (Applied Biosystems) and the TaqMan probes (Applied Biosystems) specific for murine b-actin (*Actnb*, probe n°: Mm_01205647-g1), β-2microglobulin (*B2m*, probe n°: Mm_00437762-m1) and CLEC-2 (*Clec1b*, probe n°: Mm_0183353-m1). The pre-amplification PCR reaction settings were 95°C, 10min followed by 10 cycles: [95°C, 15sec; 65°C, 4min]. These pre-amplified cDNA were diluted 1/5 with RNase-free/DnaseDNase-free water (Qiagen). The TaqMan probes based quantitative PCR were set-up on a 384 well/plate using ‘TaqMan Gene Expression Master Mix’ (Applied Biosystems) and the TaqMan probes for the murin *Actnb*, *B2m* and *Clec1b* mentioned above. The quantitative PCR reactions were run on a 7900HT quantitative PCR machine (Applied Biosystems) at 50°C, 2 min; 95°C, 10 min; 40 cycles: [95°C, 15 sec; 60°C, 1 min].

**Statistical Analysis**

All statistical analyses were performed on Prism v4.0 (GraphPad Software, CA) using two-tailed Mann-Whitney tests with 95% confidence interval.
Aknowledgements:

We are grateful to Beata Grygielska for the genotyping of Clec1b$^{flo}$ x Rosa26$^{+/creERT2}$ mice and the University of Birmingham Biomedical Services Unit for mouse technical support. We thank the Technology Hub of the University of Birmingham for providing and maintaining flow cytometers and quantitative PCR machines. We are grateful to Roger Bird and Matthew G. MacKenzie for their help and expertise to perform cell sorting. We are grateful to Caetano Reis e Sousa (Cancer Research UK, London) for providing a part of the purified anti-CLEC-2 antibody 17D9 clone used in this study. We thank Kai M. Toellner (IBR, University of Birmingham) for providing us with the Jh$^{+/+}$ k$^{-/-}$ mice. We thank Paul Harrison (CTIR, University of Birmingham) for useful discussions. This work benefited from data assembled by the ImmGen and BioGPS consortia.

This study was supported by Arthritis Research UK (19791) and the British Heart Foundation (CH/03/003, PG/11/119, RG/13/18/30563). KL was supported by the Medical Research Council.

Figure 1. CLEC-2 is present at the surfaces of peripheral blood platelets, B cells and CD11b<sup>high</sup> Gr-1<sup>high</sup> cells at steady-state. (A) Clec1b<sup>fl/fl</sup>xRosa26<sup>+/creERT2</sup> (CRE TAM) and Clec1b<sup>fl/fl</sup> littermate controls (LOX TAM) were fed tamoxifen-supplemented diet from 6-8 weeks old for 6 months. Clec1b<sup>fl/fl</sup>xRosa26<sup>+/creERT2</sup> mice (11-14 weeks old) fed conventional diet only were used as controls (CRE Control). Blood was drawn from the tail vein, the erythrocytes were lysed and the remaining leucocytes stained with fluorochrome-conjugated antibodies. CLEC-2 expression expression on platelets, B lymphocytes and myeloid cells was assessed using the 17D9 (white symbols) or INU1 (black symbols) antibody clones compared to their respective isotype controls by flow cytometry. The staining intensities are expressed by the geometric mean of fluorescence intensity (Geo.M.F.I). (B) Wild-type animals were lethally irradiated (2 x 450 rad) and injected intravenously with fetal liver cells (FL) from Clec1b<sup>+/+</sup> (WT FL) or Clec1b<sup>-/-</sup> (KO FL) E14.5 embryos. Six to eight weeks post-injection animals were challenged with 25µg LPS by intraperitoneal injection (WT FL LPS or KO FL LPS, black symbols) and compared to non-challenged animals (WT FL Control or KO FL Control, white symbols). 16-18 hours post LPS injection, blood was harvested by full exsanguination and processed as described above. Each symbol represents a sample from an individual mouse. Bars represent the means. The graphs summarize 1-3 independent experiments pooled together. Statistical significance was measured by a Mann-Whitney test with a 95% confidence interval, where: *: P<0.05; **: P<0.005; ***: P<0.0005; N.S.: not significant.
Figure 2. In secondary lymphoid organs, CLEC-2 expression by leucocytes is restricted to a subpopulation of activated DC. At 6-8 weeks old, Clec1b+/+ (WT FL) or Clec1b−/− (KO FL) foetal liver chimeras were challenged with 25μg LPS by intraperitoneal injection (WT FL LPS or KO FL LPS, black symbols) and compared to non-challenged animals (WT FL Control or KO FL Control, white symbols). 16-18 hours after LPS injections, the spleen and mesenteric lymph node (MLN) were harvested, the erythrocytes were lysed and the remaining leucocytes stained with fluorochrome-conjugated antibodies. CLEC-2 expression on (A) B cells, (B) CD11b^{high} Gr-1^{high} cells, (C) CD11b^{neg/int} DCs and (D) CD11b^{high} DCs was assessed using the 17D9 antibody compared to its respective isotype control by flow cytometry. The staining intensities are expressed as the geometric mean of fluorescence intensity (Geo.M.F.I). Each symbol represents a sample from an individual mouse and bars represent means. The graphs summarize 3 independent experiments pooled together. (E) Relative expression of Clec1b transcript in leucocytes isolated from the spleen and the MLN. C57BL/6 mice were injected intraperitoneally with PBS (white bars) or 25μg LPS (black bars). 16-18 hours later the spleen and MLN were harvested, the erythrocytes were lysed and the remaining leucocytes stained. Leucocyte populations were isolated by FACS based on the following phenotypes: T cells (T): DAPI^{neg} CD4^{neg} F4/80^{neg} CD11c^{neg} CD19^{neg} B220^{neg} CD3^{pos} CD8α/CD4^{pos}; B cells (B): DAPI^{neg} CD41^{neg} F4/80^{neg} CD11c^{neg} CD8α^{neg} CD3^{neg} B220^{pos} CD19^{pos}; NK cells (NK): DAPI^{neg} CD41^{neg} CD19^{neg} CD8α^{neg} CD3^{neg} NK1.1/NKp46^{pos}; CD11b^{pos} F4/80^{pos} cells: DAPI^{neg} CD4^{neg} CD19^{neg} CD3^{pos} CD11c^{neg} CD11b^{neg} F4/80^{pos} CD11b^{pos}; CD11b^{neg} CD11b^{int} cells: DAPI^{neg} CD41^{neg} CD19^{neg} CD3^{neg} CD11b^{int} F4/80^{pos}; cDC CD11b^{neg/int} cells: DAPI^{neg} CD41^{neg} CD19^{neg} CD3^{neg} CD11b^{neg/int}; cDC CD11b^{high} cells: DAPI^{neg} CD41^{neg} CD19^{neg} CD3^{neg} B220^{neg} CD11c^{pos} CD11b^{neg/int}; CD11b^{high} cells: DAPI^{neg} CD41^{neg} CD19^{neg} CD3^{neg} B220^{neg} CD11c^{pos} CD11b^{high}. After mRNA isolation and cDNA pre-amplification for the genes of interest, the samples were analysed by quantitative PCR. The signal for Clec1b was normalised against the housekeeping gene Actnb (β-actin). Total bone marrow (Total BM) isolated from PBS-injected mice was used as positive control while the T cells coming from these animals were used as reference to set the arbitrary unit. Each population was isolated from three to five independent cell sorting experiments including one LPS-injected and one PBS-injected mouse for each cell sorting, with the exception of the F4/80^{pos} CD11b^{int} control and LPS-stimulated cells for which n=2 experiments. Data are shown as mean + SEM. Statistical significance was measured by a Mann-Whitney test with a 95% confidence interval where: *: P<0.05; **: P<0.005; ***: P<0.0005; N.S.: not significant.
Figure 3. B lymphocyte-specific Clec1b deficiency does not affect lymphocyte homeostasis as CLEC-2 molecules on circulating B cells are exogenously derived. (A) Cervical lymph nodes (CLNs), inguinal lymph nodes (ILNs) and mesenteric lymph node (MLN) were isolated from wild-type (WT) and B-cell deficient Jh−/−κ−/− mice and imaged. The picture is representative of 5 wild-type and 6 B-cell deficient mice. Red bars represent 5 mm. (B-D) Irradiated recipient mice were reconstituted with a mix of 2x10⁵ Clec1b+/+ or Clec1b−/− E14.5 foetal liver cells and 18x10⁵ Jh−/−κ−/− bone marrow cells. 7-9 weeks later, the blood, spleen and mesenteric lymph nodes were isolated and analyzed by flow cytometry to determine (B, C) leucocyte numbers and (D) CLEC-2 expression was assessed using the 17D9 antibody compared to its respective isotype control. Each symbol represents an individual mouse and bars represent means. The graphs summarize two independent experiments pooled together. (E) Platelets and B lymphocytes were isolated from the blood, MLN and the spleen of C57BL/6 mice by FACS, based on the following phenotypes: Platelets: FSC<sup>low</sup> CD41<sup>pos</sup>, B cells: FSC<sup>hi</sup> CD41<sup>neg</sup> DAPI<sup>neg</sup> CD3ε<sup>neg</sup> CD19<sup>pos</sup>. After mRNA isolation and cDNA synthesis, the relative expression of Clec1b transcripts were analysed by quantitative PCR. The signals for Clec1b was normalised against the house-keeping gene Actnb (β-actin). Total bone marrow (Total BM) was used as positive control and reference to set the arbitrary unit. Each population was isolated from three independent cell sorting experiments, including 1-2 mice for each cell sorting, and one quantitative PCR was ran from each cell sorting. The graphs summarize these 3 independent quantitative PCRs pooled together and data are shown as mean + SEM. Statistical significance was measured by a Mann-Whitney test with a 95% confidence interval where: *: P<0.05; **: P<0.005; ***: P<0.0005; N.S.: not significant.
