(Received 7 June 2007; published 19 December 2007)

The path integral for randomly forced incompressible fluids is shown to have an underlying Becchi-Rouet-Stora (BRS) symmetry as a consequence of Galilean invariance. This symmetry must be respected to have a consistent generating functional, free from both an overall infinite factor and spurious relations amongst correlation functions. We present a procedure for respecting this BRS symmetry, akin to gauge fixing in quantum field theory. Relations are derived between correlation functions of this gauge-fixed, BRS symmetric theory, analogous to the Slavnov-Taylor identities of quantum field theory.

To be consistent with Newtonian physics, the description of fluid dynamics and turbulence must be the same in all inertial reference frames. For this reason, the role that Galilean invariance plays in the dynamics of a fluid system governed by the Navier-Stokes equation has been a major focus of study for decades [1,2]. The Galilean invariance of the Navier-Stokes equation plays an important part in the physical aspects of turbulence [3], in practical aspects of turbulence modeling [4], and even in fluid animation and computer graphics applications [5]. Among the symmetries of the Navier-Stokes equation, Galilean invariance is by far the most studied in theoretical approaches to turbulence [1,2,6–9]. The physical constraint of Galilean invariance must be taken into account in the modeling of turbulence [10], and in probability density transport equations [11]. Much of the interest has dealt with the infinite number of exact relations between different correlation functions implied by Galilean invariance, which are akin to the Ward-Takahashi identities of quantum field theory [12]. The most well known of these exact identities relates the vertex and response functions [2]. Based on this relation, various inferences have been made about the non-renormalization of the advective or inertial term in the Navier-Stokes equation [1,2,7,8,10,14–16].

In this Letter we observe that the Galilean invariant generating functional for stirred fluids [2,15,16], from which all the Ward identities are derived, possesses an overall infinite factor, which must first be extracted before this functional is well defined. We draw an analogy with Abelian gauge theory in quantum field theory, whereby the Galilean invariance is associated with gauge invariance, and so the infinity arises from integrating the fluid velocity over gauge equivalent copies (i.e., over an infinite number of independent inertial reference frames) of the same theory. To remove the infinite factor in the Navier-Stokes generating functional, the Faddeev-Popov procedure of quantum field theory [17] is used to “gauge fix” the theory, that is, to fix the theory to a single inertial reference frame. The gauge fixing results in the theory no longer appearing Galilean invariant. However, we demonstrate that this gauge-fixed (GF) theory possesses an underlying Becchi-Rouet-Stora (BRS) symmetry [12,18,19], which when invoked, restores the Galilean invariance.

This work provides a new insight into the structure of the Navier-Stokes equation. However, it is not simply a new way to express the same theory. We show that the infinite factor associated with the standard dynamic functional has associated with it much more dire consequences, in that there exist spurious relations amongst correlation functions. Explicit examples of such spurious relations are given. We then demonstrate that the gauge-fixing BRS procedure implemented here not only removes the infinite factor, but also eliminates these spurious relations, thereby rendering a well-defined generating functional for this theory. The BRS-invariant functional derived in this Letter is the consistent and correct functional for the Navier-Stokes theory that must be used to obtain reliable results.

The standard dynamic generating functional for a stirred incompressible fluid has been extensively studied for many years [2,7,8,10,14–16]. It is based on the path integral approach to classical statistical dynamics [15,20] and is given by

\[
Z = \int [DV][D\sigma] \exp \left[ -S[V,\sigma] + \int dk d\omega (J \cdot V + \Sigma \cdot \sigma) \right],
\]

where the action

\[
S[V,\sigma] = \frac{1}{2} \int dk d\omega \sigma_i(-k,-\omega)D_{ij}(-k)\sigma_j(k,\omega) - i \int dk d\omega \sigma_a(-k,-\omega) \times \left[ (-i\omega + vk^2)V_a(k,\omega) - M_{\alpha\beta\gamma}(k) \right] \times \int d\omega_1 V_\beta(k - j,\omega - \omega_1)V_\gamma(j,\omega_1).
\]

The fluid velocity is V, the conjugate field is \( \sigma \), J and \( \Sigma \) are k and \( \omega \) dependent sources. \( D_{ij}(-k) \) is the only non-

0031-9007/07/99(25)/254501(4) 254501-1 2007 The American Physical Society
vanishing cumulant of the random force, \( M_{\alpha\beta\gamma}(k) = (2i)^{-1} \{ k_\beta P_{\alpha\gamma}(k) + k_\gamma P_{\alpha\beta}(k) \} \) and \( P_{\alpha\beta}(k) = \delta_{\alpha\beta} - \frac{k_\alpha k_\beta}{k^2} \), and \( \nu \) is the bare fluid viscosity. Throughout this Letter we will work in wave-vector frequency space.

Consider a second primed reference frame moving with respect to the unprimed frame at constant velocity \( c = \hat{c} n \) where \( \hat{n} \) is a unit vector in the direction of motion. The relations between wave vector and the frequency of an event in the two frames and the transformations of the velocity and conjugate fields are given by

\[
\mathbf{k}' = \mathbf{k}, \quad \omega' = \omega - \mathbf{c} \cdot \mathbf{k},
\]

\[
\mathbf{V}(k, \omega) = \mathbf{V}'(k, \omega - \mathbf{c} \cdot \mathbf{k}) + \mathbf{c} \delta^3(\mathbf{k}) \delta(\omega),
\]

\[
\mathbf{g}(k, \omega) = \mathbf{g}'(k, \omega - \mathbf{c} \cdot \mathbf{k}).
\]

The action \( S \) and functional measure are invariant under this Galilean transformation. The Faddeev-Popov procedure of quantum field theory [12,17] is now applied to show that for \( J = \Sigma = 0 \), the functional in Eq. (1) has an overall infinite factor. For this, expressing the velocity zero mode as \( \mathbf{V}(0,0) = V_0 \delta^3(0) \delta(0) \) [21], first insert the factor of unity \( 1 = \int d\mathbf{b} \delta^3(V_0 - \mathbf{b}) \) into Eq. (1) to give

\[
Z = \int [D\mathbf{V}] [D\sigma] \int d\mathbf{b} \delta^3(V_0 - \mathbf{b}) \exp[-S[V, \sigma]].
\]

The observation is now made that the integrand in Eq. (6) is independent of \( \mathbf{b} \). To see this, consider changing from \( \mathbf{b} \rightarrow \mathbf{b} + \mathbf{a} \). Then perform a Galilean transformation with boost velocity \( \mathbf{c} = \mathbf{a} \) in Eqs. (3)–(5). The action and measure are invariant to this transformation and \( \delta^3(V_0 - (\mathbf{b} + \mathbf{a})) \rightarrow \delta^3(V_0 - \mathbf{b}) \), thus restoring the integrand to its original form. Because of the independence of the integrand on the value of the b, the \( d\mathbf{b} \) integral can completely factor out as an overall infinity as

\[
Z = \left( \int d\mathbf{b} \right) \int [D\mathbf{V}] [D\sigma] \delta^3(V_0 - \mathbf{b}) \exp[-S[V, \sigma]].
\]

The term in large parentheses on the right-hand side is the infinite factor we originally sought to isolate. At this stage one could simply eliminate this integral since it is just an overall, albeit infinite, normalization factor. In this case different choices of \( \mathbf{b} \) correspond to expressing the theory in different inertial reference frames. On the other hand, since the integrand in Eq. (6) is independent of \( \mathbf{b} \), we can also insert any function \( G(\mathbf{b}) \) into the integrand, for example, to render the \( \mathbf{b} \) integration finite. One convenient choice is \( G(\mathbf{b}) = \exp(-\frac{1}{2\xi} \mathbf{b} \cdot \mathbf{b}) \), where \( \xi > 0 \). Inserting this into Eq. (7) and now performing the \( d\mathbf{b} \) integration, leaves the GF functional

\[
Z'_{GF} = \int [D\mathbf{V}] [D\sigma] \exp[-S[V, \sigma] - \frac{1}{2\xi} V_0 \cdot V_0].
\]

In our analogy to gauge theories, all these different possibilities for \( G(\mathbf{b}) \) above would be called gauge choices.

Problems also arise if one attempts to compute any correlation function using Eq. (1). For example, consider \( \langle V_\alpha(k, \omega) V_\beta(k', \omega') \rangle \). Using the Galilean invariance of the action, this can be written as

\[
\left\langle V_\alpha(k, \omega) V_\beta(k', \omega') \right\rangle = \frac{1}{Z[0,0]} \int [D\mathbf{V}] [D\sigma] \exp(-S[V, \sigma]) \int [D\mathbf{V}'] [D\sigma'] \langle V_\alpha(k, \omega) V_\beta(k', \omega') \rangle.
\]

where the \( \int [D\mathbf{V}] \) integration is over all velocity field configurations that are not related by Galilean invariance, and for each such field configuration the \( \int [D\mathbf{V}'] \) integration is over all field configurations related to the particular field by a Galilean transformation. The expression Eq. (9) shows that using the gauge-fixed functional \( Z \), Eq. (1), the calculation of a correlation function sums over configurations from all Galilean-related reference frames, which in general will lead to an infinite, ill-defined quantity. This same situation would hold for a correlation function comprised of any combination of fields. Moreover, since these infinities are not just simple terms that factor out, it means they cannot be removed from the generating functional by simply dividing as \( Z[J, \Sigma]/Z[0,0] \).

The gauge-fixing term in Eq. (8) manifestly breaks the Galilean invariance of the action. We next demonstrate that this gauge-fixed theory possesses a symmetry akin to the BRS symmetry of quantum field theory [12,18,19], which when recognized restores the Galilean invariance of the gauge-fixed theory. We can multiply the generating functional \( Z_{GF} \) in Eq. (8) by the constant \( \int d\eta d\eta^* \exp(\eta^* \cdot \eta) \) where \( \eta \) and \( \eta^* \) are constant complex conjugate Grassmann vectors \( \eta_0, \eta^* = 0, \eta^2 = 0 \), and are independent of \( k \) and \( \omega \). For the "\( V_0^2 \) gauge" of Eq. (8) consider the following (infinitesimal) BRS transformation

\[
\delta_{BR S} V_0 = -c \zeta (\eta^* + \eta), \quad \delta_{BR S} \eta^* = \frac{i}{\xi} V_0 c \zeta, \quad \delta_{BR S} \eta = \frac{i}{\xi} V_0 c \zeta,
\]

where \( c \) is a constant with dimensions of velocity, \( \zeta \) is a real Grassmann parameter (independent of \( k \) and \( \omega \)), while all other modes of the velocity \( \mathbf{V}(k, \omega) \) and \( \sigma(k, \omega) \) transform under \( \delta_{BR S} \) as implied by Eqs. (3)–(5), except we replace the velocity boost \( \mathbf{c} \) by \( \mathbf{c} \rightarrow c \zeta (\eta^* + \eta) \). The gauge-fixed action,

\[
S_{GF} [V, \sigma, \eta, \eta^*] = S[V, \sigma] + \frac{1}{2\xi} V_0 \cdot V_0 - i \eta^* \cdot \eta,
\]

is BRS invariant: \( \delta_{BR S} S_{GF} [V, \sigma, \eta, \eta^*] = 0 \). In the gauge-fixed functional

\[
Z_{GF} = \int [D\mathbf{V}] [D\sigma] d\eta d\eta^* \exp(-S_{GF}[V, \sigma, \eta, \eta^*])
\]

\[
+ \int d\mathbf{k} d\omega (J \cdot \mathbf{V} + \Sigma \cdot \sigma + \Theta^* \cdot \eta + \Theta \cdot \eta^*),
\]

where \( \theta \) and \( \theta^* \) are constant Grassmann vector source terms; it is this BRS invariance that replaces the Galilean transformation and leads to relations amongst correlation functions, which in analogy with quantum field theory, will be called the Slavnov-Taylor identities [12,19].
To derive these, start with the above gauge-fixed functional \( Z_{GF}[J, \Sigma, \theta, \theta^*] \) and place all fields by the infinitesimal BRS transformation Eqs. (3)–(5), with \( c \rightarrow c(\eta^* + \eta) \) and Eqs. (10). Since the measure and the gauge-fixed action \( S_{GF} \) are BRS invariant, only the source terms will be displaced. Moreover, as \( c^2 = 0 \), we can easily expand the exponential. The gauge-fixed functional transforms as \( Z_{GF} \rightarrow Z_{GF} + \delta_{BRS} Z_{GF} \), where \( \delta_{BRS} Z_{GF} = 0 \) can be written as follows [21]:

\[
\left[ \frac{\delta}{\delta J_0} + \left( \frac{\delta}{\delta \theta^*_j} + \frac{\delta}{\delta \theta_j} \right) \hat{O}_j \right] Z_{GF} = 0, \tag{13}
\]

with \( \hat{O}_j = \int dk d\omega \left[ J_m^{(-)}(k) \frac{\delta}{\delta \omega} + \Sigma_m^{(-)}(k) \right] \). We now show that the gauge-fixed BRS symmetric theory Eq. (11) and the resulting Slavnov-Taylor identities in Eq. (13) are not simply a different way to write the standard generating functional Eq. (12), all spurious relations have been eliminated. At all orders higher than \( O(c) \), these all proportional to this fundamental identity Eq. (15), and so the GF-BRS functional Eq. (12) is completely free of spurious relations.

These considerations support our statement that the generating functional Eq. (12) is the correct and consistent one for this theory, and the correct expression of the Galilean invariance is the Slavnov-Taylor identities Eq. (13), found in this Letter.

Until now, we have been working with the generating functional Eqs. (12), and we have written the generating functional as \( W = \ln Z_{GF} \) and one-particle irreducible diagrams (i.e., the effective action). In this Letter, we have written the generating functional as \( \Gamma \) and the effective action as \( \Gamma \). The noise-averaged fields in the presence of the sources are denoted \( \langle \cdot \rangle_{\text{sources}} \), etc. In terms of \( \Gamma \) we can immediately write down the identity Eq. (13) in the form
0 \frac{i}{\xi} \nabla_{\xi}^0 \cdot \frac{\partial \Gamma}{\partial \eta_{\xi}} - \frac{i}{\xi} \nabla_{\xi}^0 \cdot \frac{\partial \Gamma}{\partial \eta_{\xi}^*} + (\eta_{\xi} + \eta_{\xi}^*) j \\
abla \times \int dk d\omega \left( k_j \frac{\partial V_{\xi m}^j(k, \omega)}{\partial \omega} \frac{\partial \Gamma}{\partial \eta_{\xi}^*} + j_k \frac{\partial \sigma_{\xi m}^j(k, \omega)}{\partial \omega} \right) \\
abla \times \left( \frac{\partial \Gamma}{\partial \sigma_{\xi m}^j(k, \omega)} - \delta(k) \delta(\omega) \frac{\partial \sigma_{\xi j}^m(k, \omega)}{\partial \omega} \right) \tag{16}

We now apply this formula to the problem at hand. The dependence of $\Gamma$ on $\eta$ and $\eta^*$ is simple since these constant Grassmann vector fields do not interact nor do they couple to the velocity or conjugate fields. Thus, we can immediately write $\Gamma[V_{\xi}, \sigma_{\xi}, \eta_{\xi}, \eta_{\xi}^*] = -i \eta_{\xi} \cdot \eta_{\xi} + \Gamma[V_{\xi}, \sigma_{\xi}]$, where $\Gamma[V_{\xi}, \sigma_{\xi}]$ does not depend on either $\eta_{\xi}$ or $\eta_{\xi}^*$, with the first few terms written in [22].

The pertinent identity we seek is then obtained by inserting $\Gamma$ into Eq. (16) and then differentiating this with respect to $\partial / \partial \eta^* \eta_j \partial / \partial V_{\xi}^j(k, \omega) \partial / \partial \sigma_{\xi}^j(-k, -\omega)$ followed by setting $\eta^* = \eta = V^j = \sigma^j = 0$. Note that the terms in Eq. (16) depending on the gauge parameter $\xi$ do not contribute, thus giving the identity [7,8,10,14]

$$-k_m \frac{\partial}{\partial \eta_{\xi}^*} \Gamma^{(j)}(0, 0; -k, -\Omega; k, \omega) = \Gamma^{(j)}(0, 0; 0; -k, -\Omega; k, \omega)$$

This well known identity, has been explicitly verified up to one-loop order [1,7]. The GF-BRS theory preserves this identity as it should, but this theory is moreover free of all spurious relations. In addition, the origin of this identity is seen through the GF-BRS approach as arising in the limit of vanishing mean translational velocity, but completely independent of the properties of the fluctuating velocity. This conclusion, in agreement with [13,14], is seen here in a systematic, mathematically consistent, derivation.

The implications and consequences of Galilean invariance for Navier-Stokes fluid dynamics have been outstanding questions for some time now [1,2,6–11,13,14]. The formulation of the Navier-Stokes equation subject to random forcing as a classical stochastic field theory [2,7,8,10,14–16] opens up the way to apply the systematic techniques originally developed for quantum fields [19]. This Letter has shown that a field theoretic approach provides a deep understanding of the Galilean symmetry through its close relation to gauge fixing and BRS symmetry; the constraint singling out a unique reference frame leads to a global symmetry with anticommuting parameters first used in quantum gauge field theory [18].

In summary, we have discovered a new symmetry in Galilean invariant classical stochastic field theories, which provides a powerful new way to think about the analysis of these systems. In this Letter we focused on the Navier-Stokes equation but in broader terms our analysis applies also to other Galilean invariant theories such as the KPZ equation [23], magnetohydrodynamics, and the Burgers equation. An immediate and important consequence of our result is that, within the presently understood generating functionals for these theories, there are spurious relations which our gauge-fixing procedure corrects. The treatment of a stochastic noise force, but formally our treatment is also applicable without the noise force. Our work, apart from now providing the mathematically consistent expression for functional of Galilean invariant stochastic field theories, would be important in numerical and simulation calculations of these theories.
