EDGE ARTICLE

Chemoselective Nitro Reduction and Hydroamination Using a Single Iron Catalyst

Kailong Zhu,* Michael P. Shaver* and Stephen P. Thomas*∗

The reduction and reductive addition (formal hydroamination) of functionalised nitro arenes is reported using a simple and bench-stable iron(III) catalyst and silane. The reduction is chemoselective for nitro reduction over an array of reactive functionalities (ketone, ester, amide, nitrile, sulfonyl and aryl halide). The high activity of this earth-abundant metal catalyst also facilitates a follow-on reaction in the reductive addition of nitro arenes to alkenes, affording efficient formal hydroamination of olefins under mild conditions. Both reactions offer significant improvements in catalytic activity and chemoselectivity. And the utility of these catalysts in facilitating two challenging reactions supports an important mechanistic overlap.

Introduction

The chemoselective production of aniline and aniline derivatives is a cornerstone of modern industrial chemistry. The global aniline market was valued at £6.25 billion in 2013 and will reach a gross market value of £10.17 billion by 2020.1 Aniline and aniline derivatives find use in polymers and materials (e.g. polylethylene and rubber), herbicides, bulk chemicals and dyes and pigments (e.g. indigo).2 Current preparation methods rely on precious metal-catalysed reduction of nitroarenes using high pressures of hydrogen gas, and suffer from low chemoselectivity.3 Silanes have now emerged as a hydrogen gas alternative.4 Earth abundant metal catalysis is at the fore of academic and industrial research due to the inherent availability, sustainability, low cost and low toxicity of these metals. Iron holds a unique position, offering the lowest environmental and societal impact as it is the most abundant transition metal, non-toxic and environmentally benign. Although great strides have been made in the use of iron catalysts in organic synthesis,5 the reduction of nitro groups has received little attention.6 The current state of the art often require high catalyst loadings and long reaction times to transform a limited scope of substrates with low chemoselectivity.

We recently reported the reduction of carbonyl compounds using an iron(III)-amine-bis(phenolate) catalyst 4b and silane as the stoichiometric reductant (Scheme 1, a).7 While these complexes were originally used as impressive mediators of controlled radical polymerisations,8 (Scheme 1, b) we were surprised that they also showed excellent activity and chemoselectivity for the hydrosilylation of aldehydes and ketones over a wide range of other functionalities.

Inspired by this ability of the amine-bis(phenolate) catalyst to mediate both radical and reduction events we sought to extend this reaction manifold for the reduction and reductive functionalisation of nitroarenes. If the chemoselectivity and high catalyst activity observed in the carbonyl reductions could be transferred to nitroarene reductions, the amine-bis(phenolate) system would represent a clear advance of the current iron-based reduction manifolds. Moreover, if nitro reduction is combined with radical hydrogen-atom transfer (HAT) to an alkene,9 a formal hydroamination would be possible. As recently reported,9 the iron-catalysed formal hydroamination of alkenes is an extremely powerful reaction accessible with high iron catalyst loadings (>30 mol%) and elevated reaction temperatures (60 °C) to achieve moderate yields. We postulated that increasing the rate of nitroarene reduction, and thus increasing the concentration of the intermediate nitroarene, the overall efficiency of this process could be increased and the catalyst loading lowered significantly.

Introduction

The chemoselective production of aniline and aniline derivatives is a cornerstone of modern industrial chemistry. The global aniline market was valued at £6.25 billion in 2013 and will reach a gross market value of £10.17 billion by 2020.1 Aniline and aniline derivatives find use in polymers and materials (e.g. polylethylene and rubber), herbicides, bulk chemicals and dyes and pigments (e.g. indigo).2 Current preparation methods rely on precious metal-catalysed reduction of nitroarenes using high pressures of hydrogen gas, and suffer from low chemoselectivity.3 Silanes have now emerged as a hydrogen gas alternative.4 Earth abundant metal catalysis is at the fore of academic and industrial research due to the inherent availability, sustainability, low cost and low toxicity of these metals. Iron holds a unique position, offering the lowest environmental and societal impact as it is the most abundant transition metal, non-toxic and environmentally benign. Although great strides have been made in the use of iron catalysts in organic synthesis,5 the reduction of nitro groups has received little attention.6 The current state of the art often require high catalyst loadings and long reaction times to transform a limited scope of substrates with low chemoselectivity.

We recently reported the reduction of carbonyl compounds using an iron(III)-amine-bis(phenolate) catalyst 4b and silane as the stoichiometric reductant (Scheme 1, a).7 While these complexes were originally used as impressive mediators of controlled radical polymerisations,8 (Scheme 1, b) we were surprised that they also showed excellent activity and chemoselectivity for the hydrosilylation of aldehydes and ketones over a wide range of other functionalities.

Inspired by this ability of the amine-bis(phenolate) catalyst to mediate both radical and reduction events we sought to extend this reaction manifold for the reduction and reductive functionalisation of nitroarenes. If the chemoselectivity and high catalyst activity observed in the carbonyl reductions could be transferred to nitroarene reductions, the amine-bis(phenolate) system would represent a clear advance of the current iron-based reduction manifolds. Moreover, if nitro reduction is combined with radical hydrogen-atom transfer (HAT) to an alkene,9 a formal hydroamination would be possible. As recently reported,9 the iron-catalysed formal hydroamination of alkenes is an extremely powerful reaction accessible with high iron catalyst loadings (>30 mol%) and elevated reaction temperatures (60 °C) to achieve moderate yields. We postulated that increasing the rate of nitroarene reduction, and thus increasing the concentration of the intermediate nitroarene, the overall efficiency of this process could be increased and the catalyst loading lowered significantly.

Scheme 1. Iron-catalysed reduction and radical reactions supported by Fe(III) amine-bis(phenolate) catalysts and the extension of these reactions to the reduction and reductive addition of nitroarenes.

In the context of the catalytic flexibility of the Fe(III) amine-bis(phenolate) framework, there is an obvious opportunity to develop a single catalytic system that is able to both reduce nitro compounds under mild conditions with high chemoselectivity and access a formal hydroamination of olefins at low catalyst loadings and temperatures (Scheme 1, c).

Results and discussion

Our investigations began with the development of the chemoselective nitro reduction of 4-nitroacetophenone 1a (Table 1). Triethoxysilane was selected as the stoichiometric reductant due to its low cost, ease of handling and wide availability.10 Amine-bis(phenolate) iron(III) catalysts 4a gave amine 2a in 79% yield with 7% reduction of the ketone to give alcohol 3a (entry 1). Catalyst 4b, bearing the tetrahydro-2-furanyl donating group, gave both high reactivity and chemoselectivity for amine 2a (entry 2). Solvent had a significant influence on the reaction in terms of both reactivity and selectivity. Replacing MeCN with toluene gave a significant drop in both conversion and chemoselectivity for amine 2a (entry 3). Using THF gave an even lower conversion and reduction of the carbonyl group was observed (entry 4). Ethyl acetate gave a similar result to that of toluene with regard to conversion and selectivity (entry 5). The use of PhSiH3 or Ph2SiH as the reducing agent, significantly reduced conversion and chemoselectivity (entries 6 and 7). The sterically bulky silanes Ph3MeSiH and (MeSiO)3MeSiH showed no reactivity towards either the nitro or carbonyl groups (entries 8 and 9). Reducing the amount of silane from 4.0 equivalent to 3.0 equivalent led to a longer reaction time of 8h in order to obtain comparable reduction (entry 10). As a widely used surrogate of triethoxysilane, diethoxymethylsilane gave product 2a in 90% yield together with 5% of 3a using 5 mol% of catalyst (entry 11). In consideration of the safety issue associated with triethoxysilane, this condition might be applied to large scale production.

[a] Unless otherwise noted, all reactions were carried out using 4.0 eq. of hydrosilane (1.20 mmol), 1.0 eq. of 4-nitroacetophenone (0.3 mm) 0.02 eq. of catalyst 4 (0.006 mmol) in 0.3 mL solvent at 80 °C for 4h. [b] Determined by 1H NMR using 1,3,5-trimethoxybenzene as internal standard. [c] Isolated yield. [d] 3.0 eq. of triethoxysilane was used. 8h. [e] 0.05 eq. of catalyst was used.

The substrate scope of this newly developed catalytic system was investigated using the optimised reaction conditions of 2 mol% catalyst 4b, 4.0 equivalents of triethoxysilane in MeCN (1.0 M) at 80 °C (Table 2). In all cases, good to excellent yield and chemoselectivity were obtained, demonstrating the utility of this methodology in synthesis. Industrially important anilines could be prepared from nitrobenzene in 84% isolated yield (entry 1). α-Methyl, m-methyl and, in contrast to other methods,6 even the sterically hindered 2,6-dimethyl nitrobenzene were all successfully reduced with good yields (entries 2, 3 and 4). p-(Methylthio)aniline 2f was produced from the corresponding nitroarene in excellent yield, although an 8 hour reaction time was needed (entry 5). The selective reduction of the nitro group in the presence of an ester functionality proceeded smoothly in all cases with excellent yields (entries 6, 7, 8, and 9), indicating the complete chemoselectivity and reactivity of the developed system for these challenging substrates.11 Methylsulfonyl substituted nitrobenzene 1k was also reduced with excellent chemoselectivity for the NO2 group (entry 10). In the case of 4-nitrobenzonitrile, 65% yield of amine 2i was obtained; however, 30% of the starting material was recovered, once again demonstrating the high chemoselectivity of the catalyst for the nitro group over nitrile (entry 11). The low yield of the reaction of 4-nitrobenzonitrile could be attributed to the coordination of the CN- group to the catalyst which impair the activity. To demonstrate this, 4-nitrobenzonitrile and ethyl 4-nitrobenzoate was mixed to be reduced using the optimised condition and the yield of the reduction of ethyl 4-nitrobenzoate 1h dropped dramatically from 98% to 30%.12 Halogenated nitrobenzene derivatives were also reduced chemoselectively and in good yield without any protodehalogenation13 or homocoupling14 observed (entries 12, 13 and 14). Nitroarenes 1p and 1q, bearing the strongly electron-withdrawing CF3 group, were reduced to the corresponding anilines, 2p and 2q, in 90% and 85% yield, respectively (entries 15 and 16). Nitro-substituted benzoxazole 1r was selectively reduced to corresponding amine 2r in 88% yield without any ring-opening or arene hydrogenation observed (entry 17).15 Nitrobenzene 1s, bearing an amide functionality, was also well tolerated to give the product in excellent yield (entry 18). Substrate with free alcohol gave relatively lower yield (entry 19).

[a] Unless otherwise noted, all reactions were carried out using 4.0 eq. of triethanolamine (2.40 mmol), 1.0 eq. of nitro substrate (0.6 mmol), 0.02 eq. of catalyst (0.012 mmol) in 0.6 mL MeCN at 80 °C. [b] Isolated yield. [c] Using 4.0 eq. of HSiMe(OEt)₃, 0.05 eq. of 4b, 5h. [d] Starting material recovered. [e] Yield determined by 'H NMR using 1,3,5-trimethoxybenzene as internal standard. [f] 0.04 eq of catalyst was used.

To showcase the applicability of the developed nitro reduction, we explored the reduction of academia- and industrially relevant targets. Bis(2-aminophenyl)amine 2u, which is widely used in the synthesis of N,N,N-type pincer16 or triamido17 ligands, was obtained in 80% isolated yield. This was directly comparable to the yield reported using palladium-catalysed reduction with H₂. Drug precursor 1v was chemoselectively reduced to amine 2v in 90% yield. This late stage reduction with a non-toxic metal greatly simplifies purification and trace metal removal, so making the developed method ideal for targets to be tested in vivo.18 Amidation of 2v would give 4-(pyrazole-1-yl)carboxanilides, a family of drugs that tune the activity of canonical transient receptor potential channels (TRPC) and thus control the influx of intracellular Ca²⁺ into a plethora of mammalian cell types (Scheme 2).19

[a] Reactions were carried out using 0.6 mmol of nitro compounds. [b] Isolated yield.

Having successfully developed a highly efficient silane-mediated reduction of nitroarenes, we were keen to explore if this could be combined with radical HAT for a formal hydroamination,9,20 as we hypothesised that the high reactivity of 4b for nitroene reduction would increase rates of reactions with alkenes. Strikingly, application of catalyst 4b in the formal hydroamination of alkenes using nitroene 1w and alkene 5a gave amine 6a in 75% isolated yield after Zn/HCl work-up21 using just 2.0 mol% catalyst, a 15-fold reduction in catalyst loading compared to Baran’s system. Additionally, the starting nitro substrate was fully consumed at room temperature in just 2h. 1-Chloro-2-nitrobenzene 1n gave the corresponding amine product 6b in relatively lower yield, potentially due to the halogenophilicity of the parent Fe complexes.8 Nitroarenes with methyl group were well tolerated to give the formal hydroamination product 6c while nitroene 1f, bearing the strongly electron-donating methythio group, afforded the corresponding amine 6d, both in good yields. Nitroene 1x with a free carbonyl group was also well tolerated to give the product 6e in lower yield.
but with the carbonyl functionality unchanged. Importantly, the formal hydroamination of olefin 5d could be further extended under the same reaction conditions. Reaction with 4-nitroanisole 1y followed by an intramolecular amine-carbonyl reductive amination gave the N-arylpiperidine 7a in 45% yield, indicating the potential application of this method in the preparation of N-heterocycles (Scheme 3). Deprotection of the para-methoxyphenyl (PMP) group of 7a would give 2,2,6-trimethyl piperidine which is a useful reagent for the α-alkylation of aldehydes.

[a] Reactions were carried out using 0.3 mmol of nitro compounds and 0.9 mmol of alkene. [b] 2.0 equiv of silane, 2h. [c] 1.0 equiv of silane, 1h. Isolated yield are shown in parentheses together with the donor olefin used.

Conclusions

We have developed a highly chemoselective, efficient and operationally simple amine-bis(phenolate) iron(III)-catalysed reduction of nitro compounds using triethoxysilane as the reducing agent. The system chemoselectively reduces aryl nitro groups over carbonyl, ester, imine, sulfonyl and cyano functionalities. The highly efficient formal hydroamination of alkenes has also been developed with excellent activity observed at room temperature with low iron catalyst loadings. Mechanistic studies and the investigation into the scope of catalyst 4b for reductive functionalization continue.
