Wendlebury (Alchester fortress): the 2003 season
(SP 570 203)
Eberhard Sauer

Confirmation of the main fortress-annexe theory
The main aim of the 2003 season had been to prove or
disprove the theory that the western military compound,
built in autumn AD 44, was an annexe to an (earlier?) main
fortress underneath the later town. Three separate
indications confirmed the correctness of this hypothesis.
They are discussed in the first three sections.

Indication 1: ditches of the western compound do not
continue in the area of the later town (Trenches 42 and 41)
Excavations in Trench 42 established that the southern
ditches of the western compound do not continue
underneath the later town. Furthermore, there is a strong
probability that sections of a ditch of similar dimensions
encountered in Trenches 32 and 42 are part of the same
early Roman drainage ditch. Pottery from its bottom fill in
Trench 32 suggests that it dates to the military or early
civilian period in the first century (Nick Cooper, pers.
comm; Berrington 2003). That this ditch would be parallel
to other Roman north-south running features adds strength
to the attribution of both segments to the same ditch. If so,
level values prove that the water flowed, as one would
expect, from the north to the south, following the natural
gradient. Since it would make little sense to dig a drainage
ditch across much deeper fortress ditches, it indicates that
no fortress ditches crossed the line between Trenches 32
and 42.
This suggests that our theory that the western compound
with its tree-ring-dated gate of AD 44 formed an annexe to
the main fortress underneath the town is correct. While we
established that there is no military gate underneath the west
gate of the town, it seems likely that it is slightly further to
the west in the area of the gap in the town wall ditch. The
fact that the annexe ditches do not continue leaves little
doubt that there was a main fortress whose western defences
roughly coincide with those of the later town. It is
unimaginable that such a fortress was not protected by
ditches, rampart and gates. The fact that there were
military-period west-east-running gullies in Trench 41
proves decisively that the west-east road also in this section
of the town goes back to the mid 1st century. Three or four
gullies appear to belong to this phase while a fifth
stone-lined gully is likely to be later. The outer edges of the
southern and northern drainage gullies are 6m apart (as in
Trench 20N). The absence of any traces of early timber
buildings from Trench 41, encountered the year before just
slightly further to the east in Trench 32, suggests that we
have reached the intervalum, the unoccupied space just
inside the defences. Two possibilities emerge:

1. the 14.5m wide town ditch explored in Trench 28 in 2001
incorporated not only the ditches (normally some nine
metres wide including the space between them) of the
earlier main fortress, but also the area of the earlier rampart
(perhaps as a convenient source of gravel if still existent in
the late second century).

2. The town ditch incorporates the inner ditch and the
rampart of the main fortress. The outer ditch might have
been formed by a c 3m wide ditch, 4m outside the town wall
ditch, equally explored in Trench 28 in 2001. The function
of this sterile ditch had never been clarified, but because of
its U-shaped profile and the irregular uneven base it has
previously been considered not to be military. With
hindsight the question arises whether the uneven base could
have been the result of the bottom of the ditch being
deliberately filled with sterile gravel.
Option 1 seems more likely than 2 because of what would be
an unusually wide gap (of 4m) between the two ditches in
the latter case. The outer ditch is likely to be associated with
the town wall. Further fieldwork is required for ultimate
clarification and it still seems possible that gate timbers
survive which could clarify whether the main fortress dates
to AD 43 or AD 44.

Indication 2: the water supply (Trench 41)
Five gullies were found in Trench 41 (as stated above). The
middle gully was comparable in section to the flat-bottomed
gully with slanting sides thought to be originally
timber-lined and interpreted as a water supply gully in
Trench 20N (Sauer 2001: 15). While the base in Trench 20N
had been encountered at 62.6m above sea level, it was at
62.775m at the west (east-facing) profile in Trench 41 and at
62.8m at the east (west-facing) profile. With a difference of
no less than 200mm from east to west there is no longer any
doubt that water was channelled from east to west, ie,
presumably, from the earlier main fortress to the later
annexe. This also explains why the gullies in Trenches 40, 29
and 26 (whose bottom reached a greater depth than the
water supply gully in both, Trench 41 and 20N), which
predates the earliest military buildings in this area, is
curving from the southeast to the northwest. This is a further
argument for the correctness of the theory that there was an
earlier fortress (of AD 43?) with an annexe of AD 44.

Indication 3: a double granary in the main fortress
(Trenches 49 and 48)
We established that the military timber granary explored in
2001 and 2002 is part of a double granary, the western
building measuring 13.7m by at least 16.9m and its eastern
counterpart probably being of similar size. The north-south
extent of the pair of buildings depends on how much, if
anything, has been destroyed by the later town ditch or still
awaits discovery on the other side of the Gagle Brook. There
Alchester in the prehistoric and early Roman military period

Nos. refer to trenches (20-49, 20N & E4). Only those trenches have been plotted where military, prehistoric or natural deposits have been reached. The limits of trenches exclude areas where excavations stopped at a higher level. Larger areas with straight edges are those where the results of geophysical surveys have been included in the plot.

Fig 14. Alchester.
The double granary and other features in trenches E4, 33, 34, 35, 48 and 49

Please note that more precise dating of the features will be possible after full analysis of the pottery.
can no longer be any doubt about the interpretation of the parallel timber foundation trenches as being part of military structures and their location in the south of the town thus strongly suggests that all of the 10.5 ha large Roman town was built over an earlier fortress. Together with its c 4 ha large annexe the Alchester base is almost as large as the legionary fortress at Exeter (and may have been of similar size if it extended further south).

The spacing between the timber foundation trenches for the raised floor (c 1.3m centre to centre) of the eastern granary is about twice as great as in the western, but they are in a similar alignment. The spacing in case of the eastern building are normal for a Roman granary while it is only half of what one would have expected in case of the western. This suggests that the western granary was rebuilt, but not its eastern counterpart. A possible explanation is that the garrison was reduced at some stage. The question arises whether this was when the garrison was withdrawn, presumably in the late AD 50s or early AD 60s. It seems odd that it should have been necessary to entirely demolish and rebuild a timber granary within less than 20 years rather than just re-using one in case of a reduction in the garrison. However, it has to be borne in mind that the timber buildings in the annexe also saw substantial alterations; we know that the annexe was abandoned by the mid AD 60s at the latest, thus indicating that the maximum period of occupation cannot have lasted much longer than 20 years at most. It seems unlikely that we are dealing with a complete abandonment of the site to be re-occupied later by a different garrison during the period of consolidation of Roman power in the Southeast. There is in any case no evidence for any change in the defensive perimeter after AD 44 or for the complete levelling of any part of the site. Furthermore, no single structure encountered so far has been destroyed by fire. There is no space here discuss the question as to whether or not Alchester might have been partially re-occupied in the Flavian period (cf. Howgego 2003). Alternatively, there may simply have been some structural reason why one granary had to be demolished and rebuilt, but not the other.

Revision of the interpretation of the timber buildings in the annexe (Trenches 44 and 45)
The total length (west-east extent) of the rows of rooms north of the west-east road in the annexe of AD 44 amounts now to as much as 67.3m while still no edge could be found in the west. (It is possible, but not certain, that the easternmost north-running beamslot in Trench 45 marks the eastern limit of the complex.) This renders it increasingly unlikely that they formed part of a courtyard building, especially considering that the north-south extent of 45m (or up to 48m at most allowing for a section next to the road to have been destroyed by later road-side ditches) would render this an unusually oblong ground plan for which no parallel could be found. It seems now much more likely that we are dealing with parallel barrack blocks. The width of the contubernia (double rooms for the accommodation for eight soldiers each) of c 3.5 to 5.4m is within the range known for early imperial barracks as is the total length of 9 to 10m with frequent internal subdivision (and a few hearths located in interior rooms). They are somewhat irregular in size and subdivision, but, in contrast to the contemporary barracks at Longthorpe (Frere and St. Joseph 1974: 28-33 with fig 17), their alignment is very regular. It seems possible that the centurions’ quarters were located to the west of the buildings. The question why there is a rectangular pit in place of an earlier water basin, the latter with its supply channel pre-dating the military buildings, in the area of one of the contubernia is still unresolved. What had previously been interpreted as an aisle between two parallel ranges of rooms poses a second problem with the interpretation as barrack blocks. If this was in fact the empty space between the backs of two barrack blocks, then the beamslot subdividing it in Phase 3 must have been the new back of either block or part of a new building. Yet, in this case one would have expected more room partitions to branch off from it. Notwithstanding these problems in the proposed interpretation as barracks, the overall dimensions of the complex render it increasingly unlikely that it could have been a separate annexe headquarters or another building where a large rectangular pit would be easier to explain, such as the military workshops. It is in any case clear that the area was densely occupied in the military period and that the annexe served to house troops rather than for storage purposes.

Discovery of a military-period well or other waterlogged feature (Trench 42)
We found parts of what appeared to be a circular feature within the main fortress whose upper fill was very rich in waterlogged wooden artefacts while the lower fill remains as yet unexcavated. Because of its depth below the surface and because our Trench (No 42) encompassed only parts of it, it has not been possible to excavate more than necessary to verify that it is indeed a feature with waterlogged fill with mid 1st century material from the very top. It is worth bearing in mind that latrines are frequently located in the intervallum. In the case of the equally partially waterlogged fortress of Bergkamen-Oberaden a series of rectangular basins in the intervallum have been interpreted as latrines (Kuehlborn 1992: 76-8). The circular shape is, however, more likely to point towards a well. If so, this would be the first of military date from Alchester. Whatever the correct interpretation, well or latrine, this early waterlogged feature has a high potential to give unique insights into military diet in the invasion period and other aspects of the occupation of the main fortress.

Archaeological evidence for additional defences next to the gate of AD 44 (Trench 43)
We established that the area between the ditch terminals and the south tower of the western gate of the annexe retained exceptionally well-preserved traces of sophisticated defences. A small ditch lined the south side of the road. Waterlogged remains of the bottom of vertical stakes in situ indicate almost certainly that it served as an ‘ancient equivalent to a mine field’. Their function was, presumably, similar to the lilia described by Caesar (BG 7,73). The perished upper portions of the stakes would almost certainly have been sharp and pointed, so that enemies trying to gain access to the berm between the inner ditch and the rampart or to escape from it would have been at risk of impaling their feet. This is, to my knowledge, the first such feature with surviving waterlogged remains of the stakes to be found in
The defences at the annexe gate of AD 44

the Roman Empire (though similar features above the water
table have been found elsewhere, such as at Rough Castle
on the Antonine Wall.) Negative impressions prove the
presence of three further pointed stakes at an oblique angle
to the vertical between the tower and the ditch terminal;
they formed an additional obstacle. Their tips above the
ground would have pointed to the south, away from the
gate. As one of the best-preserved defensive systems of its
kind, this is of far more than regional importance for the
history of military defences. Furthermore, these
sophisticated obstacles may well indicate that rebellion and
an attack on the fortress was regarded as a real danger or
that there might even have been guerrilla warfare. They
render it unlikely that the area was considered to be entirely
pacified at the time.

The southern defences of the fortress
No military features were found in Trench 47. The ditches
encountered in the trench were small and served drainage
purposes and/or as property boundaries. They were not
defensive. While we disproved the hypothesis that military
ditches crossed the area of Trench 47, further fieldwork is
required to clarify whether or not the main fortress extended
beyond the modern course of the Gagle Brook to the south
(as the location of the double granary in Trenches E4, 33,
34, 48 and 49 would suggest). Trial trenches in the meadow
east of Trench 47 should answer the question. Geophysical
survey has allowed us to detect a double ditch in this area,
but it is, unfortunately, unclear whether it is curving to the
north or running to the west. It is perfectly possible that this
double ditch forms the southern limit of the main fortress,
but it cannot be excluded that it served some other function,
e.g. that it was part of a minor road. The fact that it does not
continue far to the west adds strength to the former rather
than the latter hypothesis.

Discovery of important waterlogged remains (Trenches
43 and 42)
We recovered a large number of important waterlogged
artefacts and objects. They include probably dendro-datable
posts from Trench 42 and the earliest evidence for the
import of stone pine cones into Britain (Dr Mark Robinson,
pers comm) from the ditch terminals next to the AD 44 gate
of the annexe (Trench 43). These ditch terminals also
yielded a wealth of wooden artefacts, including various thin
wooden tablets and what is probably a wooden stylus. The
tablets are being conserved at Leicester under the direction
of Dr Graham Morgan and we will have to await the results
of conservation to see whether or not any of them carry
writing.

The Iron Age Banjo enclosure (Trench 46)
The section through the Banjo enclosure ditch proved to be
very rich in waterlogged material. Because of the density of
twigs and wood debris, we excavated slowly and therefore
have not reached the bottom. The pottery was, except for the
pieces from the uppermost layers, exclusively of Iron Age
date, but has not yet been analysed. To judge by differences
in the gravel concentration, there must have been a bank on
the inside of the enclosure ditch.

The colonnaded street (Trench 41)
We found the northern counterpart of the wall unearthed in
2002 and described in SMA 33. Its position and width leave
no doubt that this is a section of the parallel northern wall,
even though it had been robbed out. The correctness of the
theory of the two walls, quite possibly forming part of a
colonnaded street, leading along either side of the west-east
running road for at least 140m has thus been confirmed.

A decapitated burial (Trench 45)
We discovered a burial with the skull positioned at the feet
of the deceased. Found on the last scheduled day of the
carvings, only parts of the skeleton were uncovered and
none of the bones was exhumed. Post-mortar beheading,
doubtedly for ritual reasons, was widespread in the later
Roman period in Britain (cf. Sauer 1999: 65, 67) and other
examples have been found at Alchester before (Booth et al.
2001: 152-9 passim). It is likely that this example belongs to
the same period even though no grave goods or stratified
datable objects provided independent confirmation. This
appears to be an isolated burial rather than being part of a
cemetery since it is the only one encountered so far in the
area.

The west gate and town wall of Alchester (Trench 41)
The town wall in the area of the trench had been entirely
robbed out except for its rubble foundations. Two stones in
situ were all that survived of the upstanding masonry. By
contrast, various superimposed surfaces of the road leading
through the gate were preserved, being of little interest to
the post-Roman stone robbers. The gate opening at
foundation level was 2.95m wide corresponding roughly to
ten Roman feet. There were no traces of a widening of the
foundations (if one excludes a single irregular 0.4m wide
and 2.2m long buttress on the outside (west) of the town
wall (from 2 to 4.4m north of the gate opening). This
suggests that the gate had not been provided with any
massive flanking towers (if any towers at all), which would
have required wider foundations than the town wall (whose
foundations were three metres wide). The incorporation of
20 fragments of a Roman legionary tombstone, a fragment
of a second tombstone and of an un-inscribed sculpted stone
painted in red suggests that the town wall was erected at a
time when security concerns were greater than any respect
for the stone monuments erected by earlier generations. The
tombstone of a legionary veteran itself is of substantial
interest for the history of Roman Oxfordshire, providing the
first known biography of an inhabitant of this part of Britain.
It, furthermore, indicates that Alchester in all probability
had been the base of the Second Augustan Legion and,
initially, of Vespasian himself. It is intended to provide a
much more detailed report on this important epitaph in the
next issue of SMA. Since fragments of the tombstone were
found in the buttress and main foundations alike, we may
conclude that they are contemporary. Sections further
demonstrated that the foundations had been built at once and
that we are not dealing here with any later modification. Not
a single one of the 17 re-used stone monument fragments
whose three-dimensional position is known was found
south of the gate opening, suggesting that two separate
working parties were responsible for either side and only
one of them used spoils in this area. The re-use of spoils, an

Oxfordshire
Further evidence for a lowering of the water table (all Trenches except 44, 45 and 49)

Our fieldwork yielded further evidence that much of the unique waterlogged deposits is currently well above the summer water table. Wood was found in places over 500 mm above the present water table and at the moment still well-preserved wood was found as much as 350 mm above the present water table. The water table was distinctly lower than it had been in 2002; in the area of the granary the drop amounted to 230 mm, in the area of the west gate of the town it exceeded 315 mm. It is thus of paramount importance to continue to recover deposits which may well contain Britain's earliest handwritten documents and other unparalleled evidence for the history of the first years of the Roman conquest of Britain, before their imminent destruction in the light of a falling water table.

Acknowledgements

This article is dedicated to the memory of the late Mr Mick Miller without whose kind, dedicated and generous support the Alchester excavations could not have taken place. His deep interest in our project and his company will be sorely missed by all participants.

I would like to extend my thanks to Mrs Miller, Katie Miller and Paul Miller. I am grateful to the generous sponsors of the 2003 season, the British Academy, the Royal Archaeological Institute, the Roman Research Trust, the T W Greene Fund of the Craven Committee, the Administrators of the Haverfield Bequest and the Association for Roman Archaeology. The whole team has once again worked with commendable dedication and diligence. While there is no space to thank all members of the team individually, I have to mention Roger and Sally Ainslie, Beverley Bailey, Jenny De Bono, Steve Boscott, Gill Cox, Chris Green, Ann Griffin, Seren Griffiths, Bernard Jones, Dr Brian Molyneaux, Robin Newson, Jackie Potts, Andrew Rich, Judith Rosten, Roderick Scott, Paul Sorowka, Steve Usher-Wilson and Dr John Watterson who supervised or directed trenches, geophysical surveys or the processing of the finds. For essential contributions to the post-excavation I am indebted to Nick Cooper, Tony Gouldwell, Dr Graham Morgan, Daniel Prior, Dr Mark Robinson and Dr Richard Thomas. The 2003 season took place while I was a British Academy Postdoctoral Fellow and based at the University of Oxford as well as being an honorary fellow at the University of Leicester. I would like to thank all of these institutions as well as the University of Edinburgh where I am based now.
