We present determinations of the $B$ meson decay constant $f_B$ and of the ratio $f_{B_s}/f_B$ using the MILC collaboration unquenched gauge configurations which include three flavors of sea quarks. The mass of one of the sea quarks is kept around the strange quark mass, and we explore a range in masses for the two lighter sea quarks down to $m_s/8$. The heavy quark is simulated using Nonrelativistic QCD, and both the valence and sea light quarks are represented by the highly improved (AsqTad) staggered quark action. The good chiral properties of the latter action allow for a much smoother chiral extrapolation to physical up and down quarks than has been possible in the past. We find $f_B = 216(9)(19)(4)(6)$ MeV and $f_{B_s}/f_B = 1.20(3)(1)$.

Accurate determination of the CKM matrix of the Standard Model and tests of its consistency and unitarity constitute an important part of current research in experimental and theoretical particle physics. Experimental studies of neutral $B_d - B_s$ mixing, carried out as part of this program, are now well established and the mass difference $\Delta M_d$ is known with high precision. Uncertainty in our present knowledge of the CKM matrix element $|V_{td}|$ is hence dominated by theoretical uncertainties, the most important of which are errors in $f_B \sqrt{B_B}$, where $f_B$ is the $B$ meson decay constant and $B_B$ its bag parameter. Lattice QCD allows for first principles calculation of the hadronic matrix elements that lead to $f_B$ and $f_{B_s}/f_B$ and in recent years the onus of reducing theoretical errors in determinations of $|V_{td}|$ has been on the Lattice QCD community. In this article we address and significantly improve upon two of the errors that have plagued $f_B$ calculations on the lattice in the past, namely uncertainties due to lack of correct vacuum polarization in the simulations and errors due to chiral extrapolations to physical up and down quarks. The generation of unquenched gauge configurations by the MILC collaboration, which include effects of vacuum polarization from the strange plus two lighter dynamical quarks, has led to successful and realistic full QCD calculations of a variety of quantities involving both heavy and light quarks. Here we also take advantage of these well tested configurations. Another innovation in recent years has been to use the same improved staggered light quark action, which is being employed for sea light quarks and for light hadron physics, also for the valence light quarks inside heavy-light mesons. This has been crucial for allowing heavy-light simulations close to the real world. Chiral extrapolation requirements are now much milder than in the past thus reducing effects coming from this source of uncertainty.

In this study we work mainly with four of the "coarse" MILC ensembles with lattice spacing $a$ around 0.12fm. These have dynamical light quark masses (in units of the strange quark mass) of $m_f/m_s = 0.125, 0.175, 0.25$ and $0.5$. We have also accumulated results on two of MILC’s “fine” lattices with $a \sim 0.087$fm. On the fine lattices we use staggered valence light propagators created by the Fermilab collaboration. The heavy $b$ quark is simulated using the same NRQCD action employed in recent studies of the $\Upsilon$ system. For many of the ensembles the lattice spacing was determined from the $\Upsilon$ 2S–1S splitting. For two ensembles where $\Upsilon$ results are not available, we used the heavy quark potential variable $r_1$ measured by the MILC collaboration and based on studies of light quark masses in $\Upsilon$ we take as the physical chiral limit the point $m_s/m_q = 27.4$.

The basic quantity that needs to be calculated in decay constant determinations is the matrix element of the heavy-light axial vector current between the $B$ meson state and the hadronic vacuum. Taking, as is customary, the temporal component of the axial current, in Euclidean space and in the $B$ rest frame one has

$$
\langle 0 | A_0 | B \rangle = M_B f_B.
$$

In the last couple of years we have made considerable progress in reducing statistical errors in numerical determinations of this matrix element. We have developed better operators to create the $B$ meson state on the lattice and fit to a matrix of correlators with different smearings. Details of smearings and matrix fits are similar to those in the $\Upsilon$ spectroscopy studies of reference and will not be repeated here.

Table I summarizes results for the quantity $\Phi_q \equiv$
we show a difference between $\Phi$ and $\Phi$ (see text). Errors are statistical errors only. The fine lattice points were not included in the fit. The vertical line at $m_q/m_s = 1/27.4$ denotes the physical chiral limit.

\[ f_{B_q} \sqrt{M_{B_q}}, \] where $B_q$ denotes a "B" meson with a light valence quark of mass $m_q$. In the third column we show $\alpha^{3/2} \Phi_{q}^{(0)}$, the result for $\Phi_q$ in lattice units when only the zeroth order lattice heavy-light current $J_{q}^{(0)} = \bar{q} \gamma_5 q \Psi_q$ is used. The next column shows $\alpha^{3/2} \Phi_{q}$, our results after one-loop matching and inclusion of $1/M$ currents. All corrections to the heavy-light current at $O(\alpha_{QCD}/M)$, $O(\alpha_s)$, $O(\alpha_s \alpha/(aM))$ and $O(\alpha_s \Lambda_{QCD}/M)$ have been included. The dimension 4 current corrections that enter into the matching at this order have been discussed in [12]. The one-loop perturbative matching coefficients specific to the actions used in this study are given in [13]. One sees that the difference between $\Phi_{q}^{(0)}$ and $\Phi_q$ is small, about 2~4% on the coarse lattices and ~7% on the fine lattices. The very small change on the coarse lattices may be partially accidental. There is cancellation between the $O(\alpha_s)$ correction to the zeroth order current and the 1/$M$ corrections. The coefficient of the $O(\alpha_s)$ term switches sign as one goes from a bare $b$ quark mass of $aM_b = 2.8$ on the coarse lattices to $aM_b = 1.95$ on the fine lattices, so that the cancellation does not occur on the latter. In the last column of Table I we give results for $\Phi_q$ in GeV$^{3/2}$. The first errors are statistical and the second come from lattice spacing uncertainties. One sees that for most ensembles scale uncertainties dominate over statistical errors. The scales, $\alpha^{-1}$, employed here are, in order of the most chiral to the least chiral ensembles, 1.623(32)GeV, 1.622(32)GeV, 1.596(30)GeV and 1.605(29)GeV, respectively on the four coarse lattices and 2.258(32)GeV and 2.312(31)GeV on the two fine lattices.

### Table I: Simulation results for $\Phi_q \equiv f_{B_q} \sqrt{M_{B_q}}$. Sea (valence) quark masses are denoted by $m_f$ ($m_s$) and $u_0 = [\text{plaq}]/4$ is the link variable used by the MILC collaboration in their normalisation of quark masses. See text for definitions of the last three columns. The second error in the last column comes from uncertainties in the scale $a^{-3/2}$.

Table II shows results for the ratio $\xi_{\Phi} \equiv \Phi_s / \Phi_q$. This quantity, unlike $\Phi_q$, itself, is not affected directly by errors in the lattice spacing. Several other systematic errors inherent in $f_B$ determinations, that will be discussed in more detail below, are also cancelled to a large extent in the ratio. For instance, one sees that going from ratios of $\Phi^{(0)}$ to ratios of $\Phi$’s that include $1/M$ and one-loop matching corrections, produces almost no change at all. The data for $\xi_{\Phi}$ are plotted in Fig.1 as a function of $m_q/m_s$. The full curve comes from a fit to formulas of
staggered chiral perturbation theory ($S\chi PT$) and represents the prediction for full QCD. The vertical line at small $m_q$ corresponds to the physical chiral limit $m_q/m_s = 1/27.4$.

$S\chi PT$ for heavy-light decay constants has been developed by Aubin & Bernard in reference 10. For $\Phi_q$ their formula reads,

$$\Phi_q = c_0 (1 + \Delta_q + \text{analytic}).$$

(2)

The term encompassing the chiral logarithms, $\Delta_q \equiv \delta f_{Bq}/(16\pi^2 f^2)$, is given in 10 and includes $O(a^2)$ effects coming from taste symmetry breaking, both in the mass splittings among light-light pseudoscalars and in lattice artifact hairpin diagrams. For the ratio $\xi$ we use the ansatz,

$$\xi = 1 + (\Delta_s - \Delta_q) + \sum_{k} c_k (am_q - am_s)^k.$$  

(3)

$N_k$ was increased until $\xi_{\text{phys.}}^{(\text{phys.})}$, the fit result for $\xi$ at $m_q/m_s = 1/27.4$, and its error had stabilized (in practice $N_k = 2$ was sufficient). Other ansaetze such as the direct ratio, $1 + \Delta_s + c_1(2m_f + m_{sd}) + c_2 m_s$ ($m_{sd}$ is the sea strange quark mass which, on the coarse lattices, is slightly larger than the true strange quark mass $m_s$ we use for valence strange quarks) or simple linear fits without any chiral logarithms were also tried as were fits with all the $O(a^2)$ taste breaking terms turned off. All these different chiral extrapolations lead to values for $\xi_{\text{phys.}}^{(\text{phys.})}$ that differ at most by 3%. We fit simultaneously to the six coarse lattice points, 4 full QCD and 2 partially quenched (PQQCD) points, using full QCD and PQQCD $S\chi PT$ formulas respectively. Fig.1 shows just the full QCD curve.

The terms $\Delta_q$ involve the $B B^*\pi$ coupling $g_{B\pi}$ which is not known experimentally. We have carried out fits at several fixed values for $g_{B\pi}^2$ between $g_{B\pi}^2 = 0$ and $g_{B\pi}^2 = 0.75$. Good fits were obtained ($\chi^2$/dof $\approx 1$ or less) for $g_{B\pi}^2 < 0.5$ with $\xi_{\text{phys.}}^{(\text{phys.})}$ differing again by less than 3% in the range $\xi_{\text{phys.}}^{(\text{phys.})} = 1.21 \sim 1.24$. We have also let $g_{B\pi}$ float as one of the fit parameters and find $g_{B\pi}^2 = 0.0(2)$ together with $\xi_{\text{phys.}}^{(\text{phys.})} = 1.21(2)$. This fit result for $g_{B\pi}^2$ with the large uncertainty of $\Delta g_{B\pi}^2 = 0.2$ shows that our data is not able to determine $g_{B\pi}^2$ with any accuracy, the same message we get from the fixed $g_{B\pi}$ fits, where a range of $g_{B\pi}^2$ between zero and $\sim 2 \times \Delta g_{B\pi}^2$ all give acceptable fits. Fortunately, within this range $\xi_{\text{phys.}}^{(\text{phys.})}$ is not very sensitive to $g_{B\pi}^2$. We take as our central value for $\xi_{\text{phys.}}^{(\text{phys.})}$ the result from the floating $g_{B\pi}$ fit, which we consider the least biased fit. This fit gives the curve shown on Fig.1. We then take $\pm 0.03$ as the error due to statistics and chiral extrapolation uncertainties, and which also covers the spread we observe upon trying different ansaetze and different ways of handling $g_{B\pi}^2$. Remaining errors such as those due to discretization and relativistic corrections and higher order operator matchings not yet included, will affect $f_B$ and $f_{B_q}$ in similar ways and largely cancel in the ratio. One expects their effects to come in at the level of the corresponding error in $\Phi_q$, times $a(m_s - m_q)$. We have already seen that $1/M$ and one-loop matching corrections cancel almost completely in $\Phi_q$. Furthermore the two full QCD fine lattice points in Fig.1 fall nicely on the full QCD $S\chi PT$ curve fixed by the coarse lattice points indicating that any residual discretization errors in $\xi$ are smaller than the current statistical errors. Taking all these arguments into account, we estimate a $\sim 1\%$ further uncertainty in $\xi$ from these other sources. Our final result for $f_{B_q}/f_B = 1.20(3)(1)$.  

$$f_{B_q}/f_B = 1.20(3)(1).$$  

(4)

We emphasize that the reason the chiral extrapolation errors are small here is because the light quark action employed in this study allowed us to go down as low as $m_s/8$ and only a modest extrapolation to the physical chiral limit was required. This differs from the case with Wilson type light quarks, where simulations have typically been restricted to $m_q/m_s \geq 0.5$, i.e. to the region to the right of the heaviest data point in Fig.1.

Fig.2 shows the data points for $\Phi_q$ itself for $m_q/m_s \leq 0.5$ together with a full QCD $S\chi PT$ fit curve. For chiral extrapolation of $\Phi_q$ we use directly eq.(2) with analytic terms $c_1(2m_f + m_{sd}) + c_2 m_q$. We again carry out simultaneous fits to the coarse lattice full QCD and PQQCD points. Fits with the coupling $g_{B\pi}^2$ held fixed between 0.0 and 0.6 all lead to good fits with $\Phi_{\text{phys.}}^{(\text{phys.})}$ varying by 4%. Allowing this coupling to float gives $g_{B\pi}^2 = 0.1(5)$, which is consistent with the fixed $g_{B\pi}^2$ fit results, and
\( \Phi^{(\text{phys})} = 0.496(20) \text{ GeV}^{3/2} \) with again a 4\% error. We 
take the 4\% to be our best estimate for the combined 
error from statistics, chiral extrapolation and 
determination of \( a^{-1} \). The full QCD \( S_x \chi PT \) curve in 
Fig.2 comes from the floating \( g_{\beta \pi}^2 \) fit. We turn next to estimates of 
the other systematic errors in \( \Phi^{(\text{phys})} \).

A major source of systematic error in \( \Phi^{(\text{phys})} \) is higher 
order matching of the heavy-light current. Although the 
one-loop contributions turned out to be small (as 
described above), in fact much smaller than a naive estimate of 
\( O(\alpha_s) \sim 30\% \), we have no argument guaranteeing 
this to be true at higher orders. Hence we allow for an 
\( O(\alpha_s^2) \approx 9\% \) systematic matching error. This will be the 
dominant systematic error in our decay constant 
determination. Another source of systematic error comes from 
discretization effects. The fine lattice points in Fig.2 lie 
about 3 \sim 5\% lower than those from the coarse lattices. 
Since the statistical plus scale uncertainty errors on all 
our points range between 2 \sim 3\%, it is not obvious how 
much of this difference comes from discretization effects.

The size of fluctuations between independent coarse en-
sembles is comparable to this difference. It should also 
be noted that the difference between the coarse and fine 
lattice data would disappear if it were not for the one-
loop matching corrections (recall the 2 \sim 4\% corrections 
on the coarse lattices versus the \sim 7\% corrections on the 
fine lattices giving a 3 \sim 5\% difference in the radiative 
corrections on the two lattices). In other words it is dif-
ficult to disentangle discretization errors from radiative 
corrections. One could quote a combined discretization 
and higher order matching error again at the \sim 9\% level.

We opt instead to keep the 9\% as the pure (and dominat-
ing) \( O(\alpha_s^2) \) error and use a conventional naive estimate of 
\( O(\alpha_s) \approx 2\% \) for discretization errors. As the last non-
trivial systematic error we estimate uncertainties from 
relativistic corrections and tuning of the \( b \) quark mass \( m_b \) 
to be at the \sim 3\% level. Putting all this together we ob-
tain \( \Phi^{(\text{phys})} = 0.496(20)/(45)/(10)/(15) \text{ GeV}^{3/2} \). 
This leads to our result for the \( B \) meson decay constant of

\[
f_B = 0.216(9)/(19)/(4)/(6) \text{ GeV}. \tag{5}
\]

The errors, from left to right, come from statistics plus 
scale plus chiral extrapolations, higher order matching, 
discretization, and relativistic corrections plus \( m_s \) tuning 
respectively. Combining this result with our re-
sult for \( f_B/f_B \), eq.1, one finds \( f_B = 0.259(32) \text{ GeV} \).
This is very consistent with the direct calculation of 
\( f_B \), published earlier in \( \text{[4]} \) where we quote a value of 
0.260(29) GeV.

To summarize, we have completed a determination of 
the \( B \) meson decay constant in full (unquenched) QCD.
Our main results are given in eqns. \( \text{[1]} \) and \( \text{[4]} \). The 
use of a highly improved light quark action has led to

good control over the chiral extrapolation to physical up 
and down quarks. Better smearings have significantly 
reduced statistical errors. For the ratio \( f_B/f_B \) these 

improvements translate into an accurate final result with 
errors at the \sim 3\% level. For \( f_B \) itself other systematic 
errors not yet addressed in the present study dominate 
and the current total error is at the \sim 10\% level. The 
main remaining source of uncertainty comes from higher 
order operator matching. More studies should also be 
carried out on the fine lattices and on even finer lattices 
currently being created by the MILC collaboration, to re-
duce discretization uncertainties. Errors in the scale \( a^{-1} \) 
need to come down for all the ensembles. Improvements 
on all these fronts are underway. Calculations of the bag 
parameter \( B_H \) have also been initiated.

This work was supported by the DOE and NSF (USA) 
and by PPARC (UK). A.G., J.S. and M.W. thank the 
KITP U.C. Santa Barbara for support during the work-
shop, “Modern Challenges in Lattice Field Theory” when 
part of the present research was carried out. Simulations 
were done at NERSC and on the Fermilab LQCD clus-
ter. We thank Steve Gottlieb and the MILC collabora-
tion for making their dynamical gauge configurations 
available. We are also grateful to Jim Simone and the 
Fermilab collaboration for use of their light propagators 
on the fine lattices and to Claude Bernard for sending us 
his notes on \( S_x \chi PT \) for heavy-light decay constants.
