Identification of Plet-1 as a specific marker of early thymic epithelial progenitor cells

*Medical Research Council/ Juvenile Diabetes Research Foundation Centre Development in Stem Cell Biology, Institute for Stem Cell Research and Centre for Regenerative Medicine, University of Edinburgh, King’s Buildings, West Mains Road, Edinburgh EH9 3JQ, United Kingdom; ‡Division of Pathway Medicine, University of Edinburgh Medical School, Little France Crescent, Edinburgh EH16 4SB, United Kingdom; and †Western Australian Institute for Medical Research, Perth, Western Australia 6000, Australia

Communicated by Jacques F. A. P. Miller, The Walter and Eliza Hall Institute of Medical Research, Parkville, Victoria, Australia, November 27, 2007 (received for review October 6, 2007)

The thymus is essential for a functional immune system, because the thymic stroma uniquely supports T lymphocyte development. We have previously identified the epithelial progenitor population from which the thymus arises and demonstrated its ability to generate an organized functional thymus upon transplantation. These thymic epithelial progenitor cells (TEPC) are defined by surface determinants recognized by the mAbs MTS20 and MTS24, which were also recently shown to identify keratinoctye progenitor cells in the skin. However, the biochemical nature of the MTS20 and MTS24 determinants has remained unknown. Here we show, via expression profiling of fetal mouse TEPC and their differentiated progeny and subsequent analyses, that both MTS20 and MTS24 specifically bind an orphan protein of unknown function, Placenta-expressed transcript (Plet)-1. In the postgastrulation embryo, Plet-1 expression is highly restricted to the developing pharyngeal endoderm and mesonephros until day 11.5 of embryogenesis, consistent with the MTS20 and MTS24 staining pattern; both MTS20 and MTS24 specifically bind cell lines transfected with Plet-1; and antibodies to Plet-1 recapitulate MTS20/24 staining. In adult tissues, we demonstrate expression in a number of sites, including mammary and prostate epithelia and in the pancreas, where Plet-1 is specifically expressed by the major duct epithelium, providing a specific cell surface marker for this putative reservoir of pancreatic progenitor/stem cells. Plet-1 will thus provide an invaluable tool for genetic analysis of the lineage relationships and molecular mechanisms operating in the development, homeostasis, and injury in several organ/tissue systems.

The thymus is the central site of T cell generation (1) and therefore is critical for adaptive immunity. The cellularity of the thymus is complex. However, its specialist functions reside largely in the diverse array of thymic epithelial cell (TEC) types that form the thymic primordium that is sufficient to generate an organized functional thymus upon ectopic transplantation.

This population is identified by mAbs MTS20 and MTS24 (5, 6). Previous work from this and other laboratories has identified and characterized a key component of the thymic stroma (2–4). Previous work from which the thymus arises and demonstrated its ability to generate an organized functional thymus upon transplantation.

These thymic epithelial progenitor cells (TEPC) are defined by surface determinants recognized by the mAbs MTS20 and MTS24, which were also recently shown to identify keratinoctye progenitor cells in the skin. However, the biochemical nature of the MTS20 and MTS24 determinants has remained unknown. Here we show, via expression profiling of fetal mouse TEPC and their differentiated progeny and subsequent analyses, that both MTS20 and MTS24 specifically bind an orphan protein of unknown function, Placenta-expressed transcript (Plet)-1. In the postgastrulation embryo, Plet-1 expression is highly restricted to the developing pharyngeal endoderm and mesonephros until day 11.5 of embryogenesis, consistent with the MTS20 and MTS24 staining pattern; both MTS20 and MTS24 specifically bind cell lines transfected with Plet-1; and antibodies to Plet-1 recapitulate MTS20/24 staining. In adult tissues, we demonstrate expression in a number of sites, including mammary and prostate epithelia and in the pancreas, where Plet-1 is specifically expressed by the major duct epithelium, providing a specific cell surface marker for this putative reservoir of pancreatic progenitor/stem cells. Plet-1 will thus provide an invaluable tool for genetic analysis of the lineage relationships and molecular mechanisms operating in the development, homeostasis, and injury in several organ/tissue systems.

*Postnatal MTS20 cells were compared to E13.5 MTS20 CD45 TEC.

Genes on the initial list whose subcellular localization was not identified via annotation were then analyzed for the presence of putative transmembrane domains by manual curation. A list of nine candidates remained after these filtering steps: RIKEN cDNA 1600029D21 gene (1600029D21Rik; Plet-1); Claudin 4 (Cldn4); Claudin 7 (Cldn7); v-erb-b2 erythroblast leukemia viral oncogene homolog 3 (Erbb3); suppression of tumorigenicity 14 (St14); ATPase, Ca2+ transporting, ubiquitous (Atp2a3); frizzled homolog 3 (Fzd3); ATPase, Na+/K+ transporting beta 1 polypeptide (Atp1b1); and occludin (Ocln) [as annotated from the Affymetrix identifiers in NETAFFX, www.affymetrix.com; supporting information (SI Table 2)]. Subsequent qRT-PCR analysis of E15.5 MTS20+ vs. MTS20+ epithelium-enriched TECs validated the differential expression of all candidates tested (Table 1). However, a fold change of ≥2 was indicated for four genes, Ocln, Erbb3, Atp1b1, and St14, and these were excluded from subsequent analysis.

Identification of the MTS20 and MTS24 Antigen. To determine whether the gene(s) encoding the MTS20 or MTS24 antigen were among the remaining candidates, we next analyzed their expression by immunohistochemical and/or qRT-PCR analysis of MTS20+ epithelial cells and MTS20- epithelial-enriched cells obtained from E12.5 thymus primordia and postnatal thymi, focusing initially on the three top-ranked candidates. These analyses excluded Cldn4 and Cldn7 as either the MTS20 or MTS24 antigen, because although these proteins were broadly coexpressed with MTS20 and MTS24 at E12.5–E15.5 (Fig. 1) in postnatal thymi, MTS24+ cells formed only a minor subset of Cldn4+ and Cldn7+ cells (Fig. 1). Plet-1, however, was highly up-regulated in both E15.5 and postnatal MTS20+ TEC relative to MTS20+ CD45- stromal cells (Table 1), suggesting it as a strong candidate.

Plet-1 was previously identified via an EST screen for placental expressed transcripts, but neither its full developmental expression pattern nor function have been described (20). The expression pattern reported from E5.5 to E8.0 establishes that Plet-1 is expressed in the ectoplacental cone and extraembryonic ectoderm (E5.5–E8.0) and additionally in the ventral node at E7.5 and E8 (21). Therefore, to determine whether the spatial and temporal expression pattern of Plet-1 from gastrulation to midgestation in mouse was consistent with that of the MTS20 and MTS24 antigens, in situ hybridization (ISH) was carried out on whole embryos from E8.5 to E12.5. During this period, detectable Plet-1 expression appeared restricted to the pharyngeal endoderm and mesonephros regions (Fig. 2 A–H). In addition, weak staining was sometimes apparent in the ectoderm of the pharyngeal clefts. In the pharyngeal endoderm, expression was observed throughout the foregut at E8.5 and was then progressively restricted to the pharyngeal pouches.

These data are highly consistent with those obtained by immunohistochemical staining with MTS20 and MTS24, which E9.5 and E10.5 revealed strong expression throughout the pharyngeal endoderm and pouches (Fig. 2 I and J), consistent with reported E10.5 staining (7), and in an interlimb stripe that is likely the mesonephros component of the aorta-gonad-mesonephros region in which definitive hematopoietic stem cells arise during fetal development (22). Occasional weaker staining was also seen in the surface ectoderm of the buccal cavity and pharyngeal arches and in mesodermal cells adjacent to the pharyngeal pouches (data not shown).

To further investigate the relationship between Plet-1 expression and MTS20 and MTS24 staining, qRT-PCR analysis was performed on purified MTS20+ and MTS24− TECs. This revealed dynamic expression of Plet-1 within the developing thymus primordium; high relative expression levels were observed at E11.5 and thereafter, the level of Plet-1 decreased markedly until E14.5 (Fig. 3), corresponding to the observed drop in mean fluorescence detected on the surface of most MTS20+ cells by flow cytometry at these time points (6, 7). By E15.5, strong expression was again evident, suggesting either maintenance of high-level expression in a minor population of cells that is purified selectively at E15.5 or reinitiation of high-level expression at this time point (SI Fig. 8). These analyses were again consistent with both flow cytometric and

![Fig. 1. Expression analysis of candidates excludes Cldn4 and Cldn7. Immunohistochemical analysis showing MTS24 (blue) and (A) α-Cldn4 or (B) α-Cldn7 (red) staining in the postnatal mouse thymus. Images show sections of postnatal thymus tissue, with Cldn expression restricted to the medulla as previously described (29). The far right in A and B shows representative high-power images. Most if not all MTS24+ cells express Cldn4 and Cldn7 but are a subset of Cldn4+ and Cldn7+ cells.](image-url)
immunohistochemical analyses using MTS20 and MTS24 (SI Fig. 8 and refs. 6 and 7).

The full-length Plet-1 cDNA was therefore cloned from mouse fetal thymus and transiently expressed in COS-7 cells; the full length Cldn7 cDNA was also cloned and used as a control in subsequent analyses. Plet-1- but not Cldn7-transfected COS-7 cells specifically bound both MTS20 and MTS24 at levels consistent with transfection efficiency (shown for MTS20 in SI Fig. 9), suggesting that Plet-1 was the antigen recognized by both MTS20 and MTS24. Stably transfected Plet-1-COS-7 cell lines were subsequently generated and analyzed, confirming this binding specificity (Fig. 4 A and B).

Plet-1 has a predicted molecular mass of 23.2 kDa and, in keeping with this, probing of Western blots of membrane preparations from fetal thymic tissue with MTS20 revealed a band of ~23 kDa (Fig. 4 C). Several higher-molecular-mass bands were also observed, consistent with the presence of predicted glycosylation sites in Plet-1 (see below). A rat mAb, 1D4, was subsequently raised to Plet-1 by immunization of rats with the Plet-1-COS-7 cells. This mAb revealed a band of the same molecular weight as MTS20 by Western blotting (Fig. 4 C) and completely colocalized with both MTS20 and MTS24 in the fetal and postnatal thymus by flow cytometric and immunohistochemical analysis (Fig. 4 D–F). Collectively, these data establish that Plet-1 is the cognate antigen for both MTS20 and MTS24.

Plet-1 is an Orphan Protein of Unknown Function. To seek information regarding the likely function of Plet-1, we conducted extensive bioinformatic analyses. Database searches identified Plet-1 related sequences only in avian and mammalian species (SI Fig. 10) and revealed the existence of two splice variants in the mouse, with alternate exons 4. RT-PCR analysis indicated that “mouse1” is the major and probably only form expressed in the fetal mouse thymus (not shown), and this is also the predominant variant present in the National Center for Biotechnology Information EST database. Further analysis using SignalP and Phobius predicted an amino terminal signal sequence in all Plet sequences (SI Fig. 10). Plet-1 is annotated as having a C-terminal transmembrane (TM) region, and this region is predicted for the mouse1, rat, and hamster sequences using TMHMM. In addition, a GPI anchor was predicted by two independent prediction algorithms in mouse1, rat, and hamster, consistent with reports that the hamster orthologue of Plet-1 is GPI anchored (23). Notably, “mouse2” lacks both the GPI anchor and TM sites (SI Fig. 10), suggesting the existence of a secreted isoform. Other than these features and a number of potential glycosylation sites, we found no known functional motifs in the Plet-1 coding sequence of any species. Although ProSite identified a region of homology with Threonine-rich region/Ig and major histocompatibility complex domain/Type I antifreeze protein containing protein, this was not considered significant because of the high likelihood of this pattern arising by chance.

As described, Plet-1 is poorly conserved between species (20); only 34% identity exists between mouse Plet-1 and the human orthologue predicted by sequence. Neither MTS20 nor MTS24 bind fetal or postnatal human thymus tissue (data not shown). Although this could be explained by a lack of conserved epitopes, a recent
report has indicated suboptimal splice donor and acceptor sites at exons 2 and 3 of human Plet-1, rendering expression of its mRNA highly inefficient (20). Consistent with this, analysis of microarray datasets available in the public domain revealed no evidence of human Plet-1 expression. Therefore, to determine whether Plet-1 was expressed during human thymus development, day 54 to day 70 human fetal thymus tissue was obtained with full ethical approval and consent, and used to generate cDNA. Thymus development at these stages is equivalent to that at E9.5–E11.5 in the mouse, based on phenotypic and morphological analyses (A.M.F., L. Morris, and C.C.B., unpublished work). Extensive RT-PCR analysis of this cDNA using primers against human Plet-1 failed to reveal expression of this gene (Fig. 5A), although other thymus-specific transcripts including Foxn1 were readily detected (Fig. 5A), and the huPlet-1-specific primers amplified the appropriate fragments from human genomic DNA (Fig. 5B).

**Plet-1 Is a Marker of Pancreatic Duct Epithelium.** It was previously suggested that MTS24 might mark a common endodermal progenitor cell early in mouse development (7). Therefore, we investigated the distribution of this protein in endodermal organ primordia in further detail, focusing on the pancreas because of the importance of identifying cell types that can generate pancreatic beta cells. Consistent with the ISH analysis, no staining was detected at E9.5 or E10.5 in the midgut endoderm caudal to the pharyngeal region. This, together with the expression pattern reported in earlier development (21), indicates that Plet-1 is unlikely to mark a common endodermal progenitor. However, MTS24 staining was detected at E11.5 and from E13.5 to E15.5 in a small group of cells in the epithelial region of the pancreas (SI Fig. 11A) and was also observed in the fetal liver (not shown). In adult tissues, MTS24 has been reported to identify a novel population of keratinocyte progenitor/stem cells (14) and is known to bind several other tissues observed in the fetal liver (not shown). In adult tissues, MTS24 has been reported to identify a novel population of keratinocyte progenitor/stem cells (14) and is known to bind several other tissues (6, 7). To determine whether it may be a generic marker of epithelial stem/progenitor cells, we surveyed MTS24/Plet-1 expression in selected additional postnatal tissues. MTS24 bound epithelial cells in mammary (Fig. 6A, SI Fig. 11B) and prostate tissue (not shown), although localization was not restricted to recently described epithelial stem/progenitor pools in either tissue (24–26). In kidney, it colocalized with Cldn4 in medullary collecting ducts (Fig. 6B) (27). In the small intestine, MTS24 identified CD45<sup>−</sup> cells within Peyer’s and Crypto patches but did not bind any cells in the intestinal crypts (Fig. 6C). Staining of adult pancreas however revealed MTS24 binding to the epithelium of the major ducts, confirmed by colocalization with the duct-specific markers anti-pan cytokeratin (Fig. 6D) and DBA lectin (not shown). MTS24 therefore provides a specific cell surface marker for this cell type, which is strongly implicated as the source of facultative islet stem/progenitor cells induced in some pancreatic injury models (28, 29).

**Discussion**

The data presented identify Plet-1 as the cognate antigen for mAbs MTS20 and MTS24, which have previously been shown to identify...
Fig. 6. Expression of Plet-1 protein in selected postnatal tissues. Immunohistochemical staining of postnatal tissue with MTS24, α-CD49f, α-pancytokeratin (panK), α-CD14, as indicated. (A) Postnatal mammary gland; MTS24 stains ductal epithelial cells but is not restricted to the CD49f+ cells in the medullary collecting ducts (27). Right (merge) shows high-power image of sections in Left and Center. (B) Small intestine; MTS24 specifically identifies Peyers and Crypto Patches (arrows). Left and Center indicate representative structures; Right shows colocalization of MTS24 with CD45 in the small intestine. (D) Pancreas; MTS24 stains ductal epithelial cells, as evidenced by colocalization with α-pancytokeratin. Nuclear stain where shown is 7AAD. All images are representative of at least three separate experiments.

progenitor cell populations in the fetal thymus and postnatal skin in the mouse (6, 7, 14). This finding unifies those of Nijhof et al. (14) and Tatefuji et al. (23), who independently identified MTS24+ and Plet-1+ populations in mouse and hamster skin. In addition, they indicate MTS24/Plet-1 as a novel marker of pancreatic major duct epithelium, providing the first specific cell surface marker for this putative reservoir of pancreatic stem/stem cells (28, 29), and demonstrate MTS24/Plet-1 expression in mammary and prostate epithelial tissue and in Peycer’s and Crypto patches.

This study also identified the tight junction proteins Cldn4 and Cldn7 as candidate markers of TEC. Expression of Cldn4 has been reported in the fetal and adult mouse thymus (30), whereas Cldn7 has been reported only as a marker of terminally differentiated TECs (31), and our data therefore extend these findings. Although Cldn4 and -7 exhibit a high degree of colocalization with MTS24 at early developmental stages, in the postnatal thymus, MTS24+ cells are a minor subset of Cldn4+ and Cldn7+ cells, suggesting a possible precursor/progeny relationship between the MTS24+ cells and the broader population(s) defined by Claudin expression. These lineage relationships are of particular interest, because Cldn3 and -4, in conjunction with Ulex europaeus lectin (UEA-1), have recently been shown to mark precursors for the subset of medullary TEC that express Autoimmune regulator (AIRE1) (30), a gene that is critically required for induction of self tolerance in the maturing T cell pool.

Collectively, the reported findings will facilitate prospective isolation and functional testing of several medically important cell populations. Furthermore, they enable genetic analysis of the function, lineage potential, and molecular requirements of populations defined on the basis of MTS20 or MTS24 binding during organ/tissue development, homeostasis, and regeneration. We envisage that this advance will contribute important information to understanding of thymus, skin, and pancreas biology and of the fetal hematopoietic stem cell niche, in particular, by permitting definitive evaluation of the role of MTS24+ cells in the fetal and postnatal thymus, and of the capacity of pancreatic ductal epithelium to regenerate β cell mass.

Materials and Methods

Mice. CBAxC57BL/6 F1 mice were used for all analyses. For timed matings, C57BL/6 females were mated with CBA males, and noon of the day of the vaginal plug was taken as E0.5.

Embryo Dissection. Embryos were dissected from the uterus in either PBS or M2 medium (Sigma), then processed for ISH or placed in TRIzol (Invitrogen) for RNA extraction.

Human Fetal Tissue. Human fetal tissue was obtained with full ethical approval and consent from the Centre for Reproductive Biology, University of Edinburgh.

Antibodies. The following mAbs were used for immunofluorescence and flow cytometry: MTS20 (IgM) (8) and MTS24 (IgG2a) (5) are rat mAbs that recognize plasma membrane determinants and were a kind gift from R. L. Boyd (Monash University Medical School, Melbourne, Australia); anticytokeratin (rabbit polyclonal anti-keratin, Dako); α-CD45 (30-F11; FITC-conjugated); α-CD11b (M1/70; FITC-conjugated); α-CD31 (MEC13.3, R-PE conjugated); α-PDGFRe (APAS); and Ter119 (all BD PharMingen). 1D4 is a rat IgM raised against Plet-1, as described herein. α-Cldn4 and α-Cldn7 (Zymed) are polyclonal sera that recognize intracellular determinants; α-Cldn4 was a kind gift from M. Furuse and S. Tsukita (Kyoto University, Kyoto, Japan). Appropriate isotype-control antibodies (BD PharMingen) provided negative controls in all experiments. Unconjugated mAbs were detected by using mouse anti-rat IgM-PE (BD PharMingen), donkey anti-mouse IgG F(ab′)2-FITC, goat anti-rat IgM-Cy3, donkey anti-rat IgG-Cy3, goat anti-rat IgGM-FITC, and goat anti-rabbit IgG-FITC (all Jackson Laboratories), or goat anti-rabbit IgG-Alexa647 (Invitrogen). TO-PRO3 (Molecular Probes) or DAPI was used as a nuclear counterstain.

Flow Cytometry. Cells were dissociated to single cell suspensions and stained as described (6). Cells were analyzed on a FACSCalibur (Becton Dickinson) and by flowJo Ver. 4.4.4 (Tree Star). TO-PRO3 (Molecular Probes) or 7AAD was used to identify dead cells.

Purification of Fetal and Postnatal MTS20+ Cells. Mouse fetal thymus were microdissected, dissociated, and processed for flow cytometry as described (6). MTS20+ CD45+ Ter119− and MTS20+ CD45+ Ter119− or MTS20+ CD31+ CD45+ Ter119− PDGFRe− and MTS20+ CD31+ CD45+ Ter119− PDGFRe+ populations were isolated from fetal thymus by flow cytometric sorting, to a purity of >95% for each sample. To isolate postnatal MTS20+ and MTS20+ TEC, thymus were dissected from 2-mo-old mice and digested by using 0.125% (wt/vol) collagenase D at 37°C for 15 min (6). An initial enrichment for epithelial cells was achieved by using a Percoll gradient. Cells collected from the gradient were immunostained by using MTS20+ PE and the MTS20+ fractions within the epithelial gate isolated by flow cytometric cell sorting. These fractions were then stained with α-CD45 and α-CD11b (FITC-conjugated) and the MTS20+ CD45+ CD11b− and MTS20+ CD45+ CD11b+ fractions purified by a second sort, routinely to >95% purity; cytospin analysis of sorted cells indicated that >95% of MTS20+ cells were epithelial, based on anti-pancytokeratin staining. Flow cytometric sorting was performed by using a MoFlo (DakoCytomation).

RNA Collection. Intact total RNA was extracted from individual samples by using TRIZOL reagent (Invitrogen) or Qiagen reagent (Qiagen), according to the manufacturer’s instructions, and the quality of the RNA determined by analysis on an Agilent Bioanalyzer (Agilent Technologies). For global expression profiling, RNA samples were then pooled such that each pool contained RNA from ~1 × 10⁶ cells, DNase treated (DNA-free, Ambion), precipitated to the required concentration, and processed for Affymetrix analysis. For qRT-PCR analysis, samples were used individually or pooled as required.
CAGGFPIP (32), which was used to estimate transfection efficiency. Transient subcloned into pPyCAGIP (32) and transfected into COS-7 or CHO cells by using Cell Line Generation.

The full length sequences encoding Cldn7 or Plet-1 were subcloned into pPyCAGIP (32) and transfected into COS-7 or CHO cells by using the standard Lipofectamine 2000 (Invitrogen) protocol; vehicle-only controls were provided by parallel transfection with the EGFP expression plasmid, pPyCAGFPPIP (32), which was used to estimate transfection efficiency. Transient expression of the respective genes was tested after 60 h by immunostaining and flow cytometry. To generate stably transfected lines expressing GFP, Cldn7 or Plet-1, the cells were placed in selective medium (GMEM containing 2 μg/ml Puromycin) 24–72 h after transfection, and medium was then renewed every 24–48 h. Ten days after transfection, Puromycin-resistant colonies were picked and expanded in selective medium, and expression of the relevant protein confirmed by flow cytometric analysis.

Cloning. For cloning of mouse Plet-1 and mouse Cldn7, RT-PCR was carried out on cDNA generated from E13.5 mouse thymus RNA, with primers specific for full length mouse Plet-1 or Cldn7. PCR products were subcloned by using the T/A TOPO PCR cloning kit (Invitrogen), sequenced, by using BigDye Terminator reaction mix (ABI), and sequences analyzed by using DNASTar software (Ver. 6). The following primers were used: Plet-1F GTCGACATGGCCAACTCGGGCATGGCGACATGGCCAACTCGGCGGCGGCGTATTAGAAGAGGAGTTTACT; Plet-1R GGGCGCGCTTAGAAGAGGAGTTTACT; Cldn7F GTCGACATGGCCAACTCGGGCATGGCGACATGGCCAACTCGGCGGCGGCGTATTAGAAGAGGAGTTTACT; and Cldn7R GGGCGCGCTTAGAAGAGGAGTTTACT. 

Cell Line Generation. The full length sequences encoding Cldn7 or Plet-1 were subcloned into pPyCAGIP (32) and transfected into COS-7 or CHO cells by using the standard Lipofectamine 2000 (Invitrogen) protocol; vehicle-only controls were provided by parallel transfection with the EGFP expression plasmid, pPyCAGFPPIP (32), which was used to estimate transfection efficiency. Transient expression of the respective genes was tested after 60 h by immunostaining and flow cytometry. To generate stably transfected lines expressing GFP, Cldn7 or Plet-1, the cells were placed in selective medium (GMEM containing 2 μg/ml Puromycin) 24–72 h after transfection, and medium was then renewed every 24–48 h. Ten days after transfection, Puromycin-resistant colonies were picked and expanded in selective medium, and expression of the relevant protein confirmed by flow cytometric analysis.

Immunohistochemistry. Eight-micrometer sections were cut and either stained with hematoxylin/eosin or processed for immunohistochemistry, as described (9).

ACKNOWLEDGMENTS. We thank the Biomed Unit staff for animal care, J. Creiger for consenting for human tissue, Prof. R. Boyd for generous provision of MT20 and MT24, and Drs. T. Aebischer and V. Wilson for critical discussion and comments on the manuscript. This work was supported by the Leukaemia Research Fund (C.C.B., N.F.B., M.G.D., A.M.F.), the European Union-funded FP6 integrated project EuroStemCell (C.C.B., S.R.T., T.L.G., C.S.N., and A.P.), the Medical Research Council (C.C.B. and T.L.G.), the National Health and Medical Research Council, Australia Program Grant 305500 (to G.M.), and the Juvenile Diabetes Research Foundation (A.F., A.P., and S.R.T.).
