ABSTRACT

The Pescadillo protein was identified via a developmental defect and implicated in cell cycle progression. Here we report that human Pescadillo and its yeast homolog (Yph1p or Nop7p) are localized to the nucleolus. Depletion of Nop7p leads to nuclear accumulation of pre-60S particles, indicating a defect in subunit export, and it interacts genetically with a tagged form of the ribosomal protein Rpl25p, consistent with a role in subunit assembly. Two pre-rRNA processing pathways generate alternative forms of the 5.8S rRNA, designated 5.8SL and 5.8SS. In cells depleted for Nop7p, the 27SA3 pre-rRNA accumulated, whereas later processing intermediates and the mature 5.8SS rRNA were depleted. Less depletion was seen for the 5.8SL pathway. TAP-tagged Nop7p coprecipitated precursors to pre-rRNA processing pathways generate alternative forms of the 5.8S rRNA, designated 5.8SL and 5.8SS. In cells genetically with a tagged form of the ribosomal protein Rpl25p, consistent with a role in subunit assembly. Two Nop7p leads to nuclear accumulation of pre-60S particles, indicating a defect in subunit export, and it interacts component of at least three different pre-60S particles, and we propose that it carries out distinct functions in each of these complexes.

Keywords: nucleolus; pre-rRNA; ribosome; RNA processing

INTRODUCTION

Most steps in ribosome synthesis take place within the nucleolus, a specialized subnuclear structure. During ribosome synthesis, a complex processing pathway converts a large pre-rRNA to the mature 18S, 5.8S, and 25S/28S rRNAs (see Fig. 1B). In addition, the mature rRNA sequences within the pre-rRNA undergo extensive covalent nucleotide modification and assembly with the 80 ribosomal proteins. More than 80 nonribosomal proteins that are required for ribosome synthesis have been identified by genetic and biochemical approaches in yeast (see Kressler et al., 1999; Venema & Tollervey, 1999; Warner, 2001). Biochemical analyses in human cells have identified an even larger number of nucleolar proteins (Anderson et al., 2002), although in most cases, their function in ribosome synthesis has not yet been directly addressed. Subdomains of the human nucleolus can be identified microscopically. Transcription of the rDNA is believed to occur at the boundaries of the fibrillar centers with initial processing and pre-ribosome assembly occurring in the associated dense fibrillar component (DFC) regions. Later processing and assembly of the pre-ribosomes occurs in the surrounding granular component (GC) of the nucleolus (see, e.g., Shaw & Jordan, 1995; Scheer & Hock, 1999; Lyon & Lamond, 2000). Most analyses of subnuclear structure have been performed on vertebrates and plants, but similar structures are present in yeast (Leger-Silvestre et al., 1997, 1999).

During pre-rRNA processing, the 27SA3 pre-rRNA can be processed by two alternative pathways (Henry et al., 1994; see Fig. 1B). In the major pathway, the pre-rRNA is cleaved at site A3 by RNase MRP, forming the 27SA3 pre-rRNA. Subsequent exonuclease digestion to site B1S requires the two known 5’ → 3’ exonucleases, Xrn1p and Rat1p, and generates the 5’ end of the 27SB3 pre-rRNA and mature 5.8SS rRNA (Henry et al., 1994). An alternative, poorly understood, pathway processes the pre-rRNA at site B1L, the 5’ end of the 27SBL pre-rRNA. Both 27SB pre-rRNAs are subsequently processed, by apparently identical pathways, to generate the mature 25S rRNA and either the 5.8SS or 5.8SL rRNAs (see Fig. 1). The ratio between the two forms of 5.8S shows some variation between strains, but around 75–80% of the population is normally made up of 5.8SS, which is 8 nt shorter than 5.8SL. Similar 5’ heterogeneity is seen for 5.8S rRNA from many other Eukaryotes, including humans, Xenopus, Drosophila, and plants (Henry et al., 1994), sug-
of increased nucleolar size and ribosome synthesis in such cells. Pescadillo was localized to the nucleolus in Hela cells (Kinoshita et al., 2001) and the Schizosaccharomyces pombe homolog, SPBC19F5.05c, was also found to be nucleolar in a high throughput screen for subcellular localization of GFP fusion proteins (Ding et al., 2000). While this work was in progress, characterization of the yeast Pescadillo homolog Yph1p/Nop7p (YGR103w) was reported. YGR103w was originally published under the name of YPH1 (Kinoshita et al., 2001), but has been designated as NOP7 by the Saccharomyces genetic database. Nop7p is essential for viability and two temperature-sensitive (ts) lethal mutant alleles were reported to block growth at different steps in the cell-cycle; yph1-24 led to arrest in G1, whereas the yph1-45 allele caused G2 arrest (Kinoshita et al., 2001). G1 arrest is expected for mutations defective in ribosome synthesis, which are unable to pass the “Start” checkpoint control, but G2 arrest would not normally be predicted for a ribosome synthesis defect. In addition, Pescadillo was observed to contain a BRCT domain (Haque et al., 2000), which was originally identified in the breast and ovarian cancer gene BRCA1 and has been identified in several proteins involved in cell-cycle checkpoints and DNA repair (reviewed in Bork et al., 1997). Based on these observations, Pescadillo and Yph1p/Nop7p were proposed to perform some cell-cycle specific function.

A proteomic analysis of the human nucleolus identified 271 putative nucleolar proteins including Pescadillo (Anderson et al., 2002), the nucleolar localization of which was confirmed by YFP-tagging. A database search clearly identified YGR103w as the probable yeast homolog and we therefore analyzed its role in ribosome synthesis. While this work was in progress, the purification of a precursor to the 60S ribosomal subunit was reported that made use of a tagged form of Nop7p (Harnpicharnchai et al., 2001). This analysis did not, however, describe the effects of depletion of Yph1p/Nop7p on pre-rRNA processing or ribosome synthesis. Here we show that Nop7p is required for formation of 27SB5, and therefore of the mature 5.8S rRNA, from the 27SA3 pre-rRNA and has additional functions in subunit assembly or export.

RESULTS

Human Pescadillo and yeast Nop7p are localized to the nucleolus

A proteomic analysis of purified human nucleoli identified 271 proteins, one of which was Pescadillo (Anderson et al., 2002). To confirm this localization, an eYFP-Pescadillo construct was expressed in Hela cells by transient transfection (Fig. 2A). Comparison of the localization of eYFP-Pescadillo (shown in green; Fig. 2A4) to a DIC image (Fig. 2A1) showed its predominant lo-
Localization to nucleoli (indicated by arrowheads) with a low level of nucleoplasmic staining.

The subnucleolar distribution of eYFP-Pescadillo (Fig. 2A2) was compared to the GC marker eCFP-tagged B23/nucleophosmin (Npm1) (shown in blue; Fig. 2A3) and the DFC marker fibrillarin (shown in red; Fig. 2A5). Fibrillarin is a component of the box C+D snoRNAs (Schimmang et al., 1989) that function early in ribosome synthesis, whereas B23 is a putative assembly factor and nuclease that is believed to act later in ribosome synthesis (Biggiogera et al., 1990; Savkur & Olson, 1998). In vitro, B23 is reported to cleave a pre-rRNA reporter within ITS2 (Savkur & Olson, 1998), at a site potentially equivalent to C2 in the yeast pre-rRNA. Fibrillarin is concentrated in the DFC whereas B23 was reported to localize to the periphery of the DFC and the GC based on immuno-EM (Biggiogera et al., 1990), consistent with a later role for B23 in nucleolar ribosome maturation.

The distribution of eYFP-Pescadillo resembled that of eCFP-B23, but was distinct from that of fibrillarin. eYFP-Pescadillo and eCFP-B23 were largely excluded from the DFCs (one

**FIGURE 2.** Nucleolar localization of Pescadillo and Nop7p. **A:** Localization of human Pescadillo compared with known nucleolar markers. (1, 4) Hela cells were fixed 16 h after transfection with EYFP-Pescadillo. Comparison to the DIC image (1) shows localization of eYFP-Pescadillo (4; green) to nucleoli (arrowheads). 2, 3, 5, and 6: As markers for subnucleolar distribution, the EYFP-Pescadillo transfected cells (2; green) were cotransfected with the granular component protein ECFP-B23 (3; blue) and decorated with antibodies directed against the dense fibrillar component (DFC) protein fibrillarin (5; red). Scale bar = 5 μm. **B:** Localization of Nop7p. The GAL::nop7-TAP strain also expressing the nucleolar marker DsRedNop1p was examined by indirect immunofluorescence using an anti-protein A antibody coupled to FITC. Also shown is the position of the nucleus visualized by DAPI staining and a wild-type control strain.
Yeast Pescadillo is a pre-rRNA processing factor

629

of which is indicated by an arrow) and concentrated in the surrounding area, which presumably corresponds to the GC. The distribution of eYFP-Pescadillo is consistent with a late role in nucleolar ribosome synthesis. The essential yeast protein Nop7p (YGR103w) is 40% identical to human Pescadillo. To determine whether Nop7p is also nucleolar, it was epitope tagged with a tandem-affinity purification (TAP) construct (Rigaut et al., 1999) using a one-step PCR protocol (see Materials and Methods). The tagged construct was integrated at the NOP7 locus under the control of the GAL10 promoter and is the only source of Nop7p. The host strain, YDL401, has reduced galactose permease activity leading to reduced GAL induction (Lafontaine & Tollervey, 1996). This eliminates the overexpression generally seen with GAL-regulated constructs and allows faster appearance of phenotypes following transfer to glucose medium. The GAL::nop7-TAP cells exhibited no detectable growth defect on permissive RSG medium, showing the fusion construct to be fully functional (data not shown).

Yeast Nop7p is required for 60S subunit export and interacts genetically with GFP-tagged Rpl25p

To examine the possible functions of Nop7p in ribosome synthesis, its expression was placed under the control of a repressible GAL10 promoter using a one-step PCR technique in strain YDL401 (see Materials and Methods). Growth of the GAL::nop7 strain was not clearly different from the isogenic wild-type strain on RGS medium, but was progressively slowed following transfer to glucose medium, commencing around 6 h after transfer (Fig. 3A). The yph1-45 allele of NOP7 is reported to lead to a G2 arrest phenotype, consistent with a specific cell-cycle defect (Kinoshita et al., 2001). However, microscopic inspection of the GAL::nop7 strain following transfer to glucose medium showed only the accumulation of unbudded cells, even after 24 h, indicating arrest in G1 (data not shown). This is the expected phenotype for a defect in ribosome synthesis that results in the inability to pass the “Start” checkpoint.

Several recent studies have made use of fusions between ribosomal proteins and GFP to follow the ex-

FIGURE 3. Nop7p is required for 60S subunit export and interacts genetically with GFP-tagged Rpl25p. A: Growth curves of GAL::nop7 strains following transfer to glucose medium, with and without expression of Rpl25p-eGFP. Strains were pregrown in RGS medium and transferred to glucose medium for the times indicated. Strains were maintained in exponential growth by dilution with pre-warmed medium. Cell densities measured by OD600 are shown corrected for dilution. (■) Wild-type; (+) GAL::nop7; (●) GAL::nop7: rpl25.10-GFP; (▲) GAL::nop7: rpl25.4-GFP. B: Subcellular distribution of Rpl25-eGFP in a GAL::nop7 strain. Rpl25-eGFP was examined by fluorescence microscopy during growth in RGS medium and following transfer to glucose medium for 2 and 8 h. The position of the nucleus was visualized by DAPI staining, which also stains the cytoplasm more weakly due to the presence of mitochondria. In the merged image, DAPI staining is shown in red and Rpl25-GFP is in green.
with low-molecular-weight RNAs showed progressive reduction in the levels of the 7S and 6S pre-rRNAs following transfer of the GAL: nop7 strain to glucose medium (Fig. 4Bb). The level of the mature 5.8S was also reduced (Fig. 4Bc), and the reduction in 5.8S_S appeared slightly greater than for 5.8S_L. The pre-rRNA that extends from A_2 to C_2 was not accumulated during Nop7p depletion (Fig. 4Ba), in contrast to the recently reported effects of depletion of another processing factor, Ssf1p (Fatica et al., 2002).

**Nop7p is required for pre-rRNA processing**

The effects of depletion of Nop7p were assessed by Northern hybridization (Fig. 4), primer extension (Fig. 5), and pulse-chase labeling (Fig. 6).

Depletion of Nop7p resulted in mild accumulation of the 35S primary transcript and the appearance of low levels of the 23S RNA, but had little impact on levels of the 27SA_2 or 20S pre-rRNAs, or the mature 18S rRNA (Fig. 4A). In contrast, the level of the 27SB pre-rRNAs was clearly reduced by 8 h after transfer to glucose medium and the mature 25S rRNA was depleted over time.

Analysis of low-molecular-weight RNAs showed progressive reduction in the levels of the 7S and 6S pre-rRNAs following transfer of the GAL: nop7 strain to glucose medium (Fig. 4Bb). The level of the mature 5.8S was also reduced (Fig. 4Bc), and the reduction in 5.8S_S appeared slightly greater than for 5.8S_L. The pre-rRNA that extends from A_2 to C_2 was not accumulated during Nop7p depletion (Fig. 4Ba), in contrast to the recently reported effects of depletion of another processing factor, Ssf1p (Fatica et al., 2002).

**FIGURE 4.** Northern analysis of the effects of Nop7p depletion on pre-rRNA processing. Lanes 1 and 2: wild-type strain in RGS medium and 24 h after transfer to glucose. Lanes 3–7: GAL::nop7 strain in RGS medium and after transfer to glucose medium for the times indicated. A: (a) Hybridization with probe 003, complementary to ITS1 upstream of A_2. (b) Hybridization with probe 020, complementary to the 5.8S/ITS2 boundary. (c) Hybridization with probe 007, complementary to the 25S rRNA. (d) Hybridization with probe 002, complementary to ITS1 upstream of A_2. (e) Hybridization with probe 008, complementary to 18S rRNA. B: (a) Hybridization with probe 003, complementary to the 5.8S/ITS2 boundary. (c) Hybridization with probe 007, complementary to the 5.8S/ITS2 boundary. (c) Hybridization with probe 017, complementary to 5.8S rRNA. (d) Hybridization with probe 041, complementary to S5 rRNA. RNA was separated on a 1.2% agarose/formaldehyde gel (A) or 8% polyacrylamide/urea gel (B). Probe names are indicated in parentheses on the left.
5.8S\textsubscript{S} is processed from the 27SB\textsubscript{S} pre-rRNA, whereas 5.8S\textsubscript{L} is processed from 27SB\textsubscript{L} (see Fig. 1B). To determine the levels of the 27SB species, they were analyzed by primer extension (Fig. 5A) using an oligo hybridizing within the 3’ region of ITS2 (oligo 006; see Fig. 1A). Following growth of the GAL::nop7 strain on glucose medium, the level of 27SB\textsubscript{S} was clearly reduced relative to 27SB\textsubscript{L}, as shown by the primer extension stops at B\textsubscript{1S} and B\textsubscript{1L}, respectively (Fig. 5A, lane 4). Consistent with the northern analysis, little alteration was seen in the level of 27SA\textsubscript{2}, as shown by the primer extension stop at A\textsubscript{2}. In contrast, the level of 27SA\textsubscript{3}, shown by the stop at A\textsubscript{3}, was substantially elevated. Using a primer hybridizing within the mature 25S rRNA (oligo 007; see Fig. 1A), slight accumulation was seen for the primer extension stop at site C\textsubscript{2}, the 5’ end of the 26S pre-rRNA (Fig. 5B). This effect was weak, however, and its significance is unclear.

Pulse-chase analysis with [H\textsuperscript{3}]-uracil was performed 16 h after transfer to glucose minimal medium (Fig. 6). Comparison of the wild-type and GAL::nop7 strains showed that accumulation of the 5.8S rRNA was mildly delayed.

Together these data show that depletion of Nop7p resulted in reduced exonuclease digestion from site A\textsubscript{3} to site B\textsubscript{1S}. In consequence, the level of the 27SA\textsubscript{3} pre-rRNA was substantially increased, whereas the 27SB\textsubscript{S} pre-rRNA was depleted together with the 7S\textsubscript{S} and 6S\textsubscript{S} pre-rRNAs, leading to reduced accumulation of the mature 5.8S\textsubscript{S} rRNA. The 5’ end of the 25S rRNA is also generated by exonuclease digestion (Geerlings et al., 2000; see Fig. 1B), but this did not appear to be strongly affected, as only a small increase was seen in the primer extension stop at site C\textsubscript{2}. The mild effects on 35S processing are likely to be indirect, as many mutations that inhibit synthesis of 60S subunits result in partial inhibition of the early pre-rRNA processing steps (for further discussion see Venema & Tollervey, 1999).

Nop7p is associated with pre-rRNAs from both processing pathways

To determine whether Nop7p associated specifically with the 27SB\textsubscript{S} branch of the processing pathway, co-precipitated RNAs were analyzed by northern analysis and primer extension. Northern hybridization (Fig. 7A,B) showed that the 27SB and 7S pre-rRNAs coprecipitated with Nop7-TAP, but were not detectably recov-
We show here that the yeast homolog of Pescadillo is required for the 5'->3' exonuclease digestion that generates the 5' end of the major, short form of the 5.8S rRNA. Depletion of Nop7p also resulted in strong synergistic inhibition of growth in the presence of a GFP-tagged form of ribosomal protein Rpl25p, indicating an additional role in 60S ribosome assembly. Nuclear accumulation of Rpl25-GFP has been used as a marker for a defect in nuclear export of pre-60S ribosomal particles (ribosome export or rix phenotype; Gadal et al., 2001b), and this was also observed following Nop7p depletion. We conclude that Nop7p is required for a specific pre-rRNA processing step as well as correct pre-60S assembly and nuclear export.

During the course of this work, Nop7p was shown to be a component of at least three different pre-ribosomal complexes with substantially different protein composition, as well as differences in pre-rRNA components (Baßler et al., 2001; Harnpicharnchai et al., 2001; Fatica et al., 2002; see Fig. 8). These analyses allow us to propose a correlation between the pre-ribosomal particles with which Nop7p is associated and the distinct defects in ribosome synthesis that are seen on its depletion.

The earliest pre-60S particle with which Nop7p is known to be associated is pre-60S E1. This complex is also associated with the 27SA2, 27SA3, and 27SB prerRNAs (Fatica et al., 2002) and it is therefore very likely that Nop7p is required for processing from 27SA3 to 27SB within the pre-60S E1 particle.

A fast acting, dominant negative phenotype is associated with the expression of a GFP-tagged form of the ribosomal protein Rpl25 in strains depleted of Nop7p. The fact that expression of Rpl25-GFP is dominant inhibiting an additional role in 60S subunit assembly and export.

FIGURE 7. Analysis of RNAs coprecipitated with TAP-tagged Nop7p. Lane 1: Total RNA control (5 µg). Lane 2: Precipitate from a wild-type control strain. Lane 3: Precipitate from a strain expressing Nop7-TAP. A: Northern hybridization of high-molecular-weight RNA separated on a 1.2% agarose/formaldehyde gel. B: Northern hybridization of low-molecular-weight RNA separated on an 8% polyacrylamide/urea gel. C: Primer extension analysis. Nop7-TAP was immunoprecipitated from cell lysates using IgG agarose, with release of bound RNA–protein complexes by cleavage of the protein A linker by TEV protease. RNA was recovered from the released material, and from a mock-treated, isogenic wild-type control strain. Oligonucleotides used are indicated in parentheses. The preparation used in C is different from that used for A and gave lower recovery efficiency.

FIGURE 8. Model for the roles of Nop7p in 60S subunit biogenesis. Outline pathway of biogenesis of 60S and 40S ribosomal subunits, modified from Fatica et al. (2002). This model indicates the presence of Nop7p in three different pre-60S complexes designated E1, E2, and M, which can be correlated with the different functions deduced for Nop7p. Pre-60S E2 contains the 27SA2 pre-rRNA, the processing of which is defective in strains lacking Nop7p. Rpl25p is not present in pre-60S E1, but joins the pre-60S E2 particle, and the defect in Rpl25p assembly is therefore predicted to occur at this step. The pre-60S M complex contains numerous factors required for 60S subunit export as judged by the nuclear retention of a Rpl25-GFP reporter construct, and Nop7p is likely to be required during the acquisition of export competence within this complex.
Yeast Pescadillo is a pre-rRNA processing factor

633
dicates that, in its presence, the wild-type Rpl25p is no longer able to support growth. Notably, the inhibition of growth was much more rapid and complete than would be expected for a strain that was simply unable to synthesize new ribosomes due to pre-rRNA processing defects. Many such mutants have been analyzed (reviewed in Venema & Tollervey, 1999) and predominantly show a gradual increase in doubling time, as preformed ribosomes are depleted by growth. The very rapid onset of growth inhibition, seen in the Nop7p-depleted strain expressing Rlp25-GFP, indicates that this does not require substantial depletion of the pre-existing ribosome pool. We speculate that production of defective subunits prevents the remaining, otherwise functional, ribosomes from carrying out efficient translation. The pre-60S E1 complex lacks Rpl25p, which is added only to the pre-60 E2 particle (Harnpicharnchai et al., 2001; Fatica et al., 2002). We therefore predict that the genetic interaction between GAL::nop7 and Rpl25-GFP reflects a requirement for Nop7p in the correct assembly of Rpl25p, and perhaps other factors, with the pre-60S E2 complex.

Several recent studies have made use of a fusion between Rpl25p and GFP to follow the export of 60S ribosomal subunits from the nucleus to the cytoplasm (Bassler et al., 2001; Gadal et al., 2001a, 2001b; Ho et al., 2000; Milkereit et al., 2001; Fatica et al., 2002). There is considerable data showing that free r-proteins do not accumulate in the absence of ribosome synthesis. The accumulation of Rlp25-GFP has therefore been taken as evidence for the accumulation of pre-ribosomal particles in the nucleoplasm, indicating a defect in their export. This assay has defined a late pre-ribosomal particle (pre-60S M in Fig. 8), all tested components of which are required for export of 60S subunit export. These include Nug1p, Nug2p, Noc2p, Noc3p, and Rix1p as well as Nop7p itself (Bassler et al., 2001; Gadal et al., 2001a, 2001b; Milkereit et al., 2001). Mutations in any of these proteins leads to defects in export, suggesting a requirement for the intact structure of this pre-ribosomal particle. Because multiple components of this complex are required for subunit export, we predict that export competence is established within this particle, and that this activity requires Nop7p.

Mutations in Nug1p, Nug2p, Noc2p, Noc3p, or Rix1p did not result in pre-rRNA processing defects similar to Nop7p depletion or synergistic interactions with Rpl25-GFP (Bassler et al., 2001; Milkereit et al., 2001) indicating that these are distinct activities. Moreover, Nug1-TAP did not coprecipitate 27SA2 or 27SA3 (Bassler et al., 2001; E. Petfalski & D. Tollervey, unpubl. observations) indicating that it associates with the pre-rRNA particle only after processing at these sites is complete. Depletion of a specific component of the pre-60S E1 complex, Ssf1p, also did not interact genetically with Rpl25-GFP and did not inhibit subunit export as judged by nuclear accumulation of Rpl25-GFP (Fatica et al., 2002). We therefore propose that the roles of Nop7p in pre-rRNA processing, assembly, and export are distinct and performed within different pre-ribosomal particles (see Fig. 8).

Pescadillo is a multifunctional protein

Pescadillo was isolated as a mutation affecting embryonic development (Allende et al., 1996) and a mutant allele of the yeast gene resulted in growth arrest in G2 (Kinoshita et al., 2001), consistent with a specific defect in cell-cycle progression. Yeast Yhp1p/Nop7p is also reported to interact with Yvh1p (Sakumoto et al., 2001), a protein-tyrosine phosphatase with a postulated role in the regulation of sporulation and meiosis.

There are clear precedents for proteins that function both in cell-cycle progression and ribosome synthesis. Exit from mitosis in budding yeast requires a group of proteins, including the phosphatase Cdc14p, which down-regulate cyclin-dependent kinase activity. Cdc14p is sequestered in the nucleolus in the RENT (regulator of nucleolar silencing and telophase) complex with Sir2p and Net1p, which serves to anchor the complex (Shou et al., 1999). In addition, Net1p is required for the maintenance of normal nucleolar structure and its binding stimulates RNA polymerase I (Shou et al., 1999, 2001). These nucleolus-specific functions of Net1p can be separated genetically from its cell-cycle functions in the RENT complex. In human cells, the nucleolar p14/ARF protein binds and sequesters the negative regulator of p53 activity, Mdm2 (Tao & Levine, 1999; Weber et al., 1999; Zhang & Xiong, 1999). Free Mdm2 ubiquitinates p53 and transports it to the cytoplasm where it is degraded by the proteosome (Fuchs et al., 1998; Geyer et al., 2000), and the nucleolar sequestration of Mdm2 contributes to the inhibition of this activity by ARF. Mouse Pescadillo was identified by its up-regulation in cells lacking p53 (Kinoshita et al., 2001), but other interactions with the p53 system have not been reported.

The available data suggest that yeast Nop7p may function both in ribosome synthesis and in cell-cycle regulation. Whether its role in the cell cycle involves other protein components of the pre-ribosomal particles or a different set of interactions remains to be determined.

MATERIALS AND METHODS

Strains

Growth and handling of Saccharomyces cerevisiae were by standard techniques. GAL-regulated strains were pregrown in RGS medium, containing 2% raffinose, 2% galactose, and 2% sucrose, and harvested at intervals following a shift to medium containing 2% glucose. Strains for pulse-chase analysis were pregrown in minimal RGS medium lacking uracil and shifted to minimal glucose medium lacking uracil. Strains for
immunofluorescence studies were grown in minimal glucose medium lacking leucine.

Yeast strains used and constructed in this study are listed in Table 1. Conditional mutants under the control of the repressible GAL10 promoter were generated by one-step PCR strategy in the strains YDL401 and BMA64 (Lafontaine & Tollervey, 1996). Transformants were selected for His+ prototrophy and screened by PCR. TAP-tagged strains were constructed by one-step PCR strategy in the GAL-mediated strain GAL::nop7 (Rigaut et al., 1999). Transformants were screened by immunoblotting and PCR.

TAP-tagged strains were transformed with pUN100Ds RedNop1 (kindly provided by E. Hurt and U. Heidelberg) to allow ready identification of the nucleolus, and pYEplac195-L25-egfp to look at nuclear export of 60S ribosomal subunits.

For construction of eYFP-egfp, complementary DNA of human Pescadillo gene (GI:2194202) was isolated by PCR amplification from Marathon-Ready Hela cDNA library (Clontech) using specific primers with BglII and EcoRI restriction sites attached to the 5’ and 3’ primer, respectively. The amplified fragment was subsequently cloned to the BglII-EcoRI fragment of eYFP-C1 and verified by DNA sequencing.

RNA extraction, northern hybridization, and primer extension

RNA was extracted as described previously (Tollervey & Mattaj, 1987). For high-molecular-weight RNA analysis, 7 μg of total RNA were separated on a 1.2% agarose gel containing formaldehyde and transferred for northern hybridization as described previously (Tollervey, 1987). Standard 6% or 8% acrylamide-8 M urea gels were used to analyze low-molecular-weight RNA species and primer extension reactions. Primer extensions were performed as described previously (Beltrame & Tollervey, 1992) on 5 μg of total RNA using primers 007 and 006.

For pre-rRNA and rRNA analysis the following oligonucleotides were used:

002: 5’-GCTCTTTGCTTTGCC;
003: 5’-TGTTACCTCGGAGGCC;

Immunofluorescence

For localization of yeast Nop7p, cells were grown in selective medium to midexponential phase, fixed by incubation in 4% (v/v) formaldehyde for 30 min at 25 °C, and spheroplasted. Immunofluorescence was then performed as described previously (Grandi et al., 1993; Bergès et al., 1994). Protein A fusions were detected with a rabbit anti-Protein A antibody (Sigma) and a secondary goat anti-rabbit antibody coupled to FITC (Sigma) at 1:1,000 and 1:200 dilutions, respectively. To stain nuclear DNA, DAPI was included in the mounting medium (Vetashield, Vector Laboratories). Cells were viewed on a Zeiss Axioskop microscope.

Cells containing pYE195-Rpl25-eGFP were grown in SD-LEU to midexponential phase, fixed in 4% (v/v) formaldehyde for 30 min, and pelleted. Cells were resuspended in 100 mM KH2PO4/K2HPO4/1.1 M sorbitol and mounted onto slides using moviol, containing DAPI. To detect Rpl25-eGFP in vivo in the fluorescence microscope, the GFP-signal was examined in the fluorescence channel of a Zeiss Axioscope microscope (Hurt et al., 1999). Pictures were obtained with SmartCapture VP.

The localization of eYFP-Pescadillo was determined after transient transfection into Hela cells. EYFP-egfp and eCFP-B23 were cotransfected for 6 h using Effectene (Quiagen) according to the manufacturer’s protocol and fixed after 42 h using 3.7% paraformaldehyde in CSK buffer. Cells were permeabilized and decorated with antibodies against dense fibrillar component marker fibrillarin (72B9) and the granular component marker B23 (anti-B23). Cells were imaged using a Zeiss LSM410 confocal microscope or a Zeiss DeltaVision Restoration microscope (Applied Precision, Inc.). Images presented here are maximal projections of the entire nuclear fluorescence.

Immunoprecipitation of GAL::nop7-TAP

For immunoprecipitation of GAL::nop7-TAP, cells were grown in YPgal to OD600 = 2 and lysed in buffer A (150 mM KAc, 20 mM Tris-Ac, pH 7.5, 5 mM MgAc) with 1 mM DTT, 0.5% Triton X-100, 2.5 mM vanadyl-ribonucleoside complexes (VRC), and 5 mM PMSF (phenylmethylsulphonylfluoride) at

Yeast Pescadillo is a pre-rRNA processing factor

4 °C using glass beads (Sigma). Immunoprecipitation with rabbit IgG agarose beads and subsequent TEV cleavage were performed as described (Rigaut et al., 1999). RNA was extracted with buffer AE/phenol-chloroform, ethanol precipitated (Schmitt et al., 1990), and analyzed by northern hybridization and primer extension.

Pulse-chase labeling experiments

Pulse-chase labeling of pre-rRNA was performed as previously described (Tollervey et al., 1993) using 100 μCi [5,6-3H]uracil (Amersham) for 2 min at 30 °C. Unlabeled uracil was added to a final concentration of 240 μg/ml. Samples (1 mL) were taken, transferred to microcentrifuge tubes at room temperature, and spun for 10 s at full speed in an Eppendorf centrifuge. Cell pellets were frozen in liquid N2. Total RNA was extracted with buffer AE/phenol-chloroform and ethanol precipitated (Schmitt et al., 1990). [3H]-labeled pre-rRNA and rRNA was resolved on 1.2% agarose gels for high-molecular-weight RNAs and 8% acrylamide-8 M urea gels for low-molecular-weight RNAs. RNA was transferred to Hybond-N+ Nylon membranes (Amersham), dried, and exposed to X-ray film for 10 days at −80 °C with an intensifying screen.
