UK Trainee Sport Psychologists’ Perspectives on Developing Professional Judgement and Decision-Making Expertise during Training.

Date of Re-submission: 19th February 2019
Developing Decision-Making 2

Abstract

The research team explored UK trainee sport psychologists’ perspectives on developing professional judgment and decision-making (PJDM) expertise during their British Psychological Society (BPS) Qualification in Sport and Exercise Psychology (QSEP; Stage 2). An assorted analysis approach was adopted to combine an existing longitudinal qualitative data set with the collection and analysis of a new qualitative data set. Participants (female, \( n = 1 \); and male, \( n = 6 \)) were interviewed 4 times over a 3-year training period, at minimum yearly intervals. Interviews were transcribed verbatim, and reflexive thematic analysis applied to transcripts using the theoretical concepts of PJDM. Experience, analytical reasoning, and observation of other practitioners’ practice was useful for developing PJDM expertise. PJDM expertise might be optimised through the use of knowledge elicitation principles. For example, supervisors could embed critical cues within the anecdotes they share to expand the experience base that trainees can draw from when making decisions.

Keywords: professional training, judgement, decision-making, cognition
UK Trainee Sport Psychologists’ Perspectives on Developing Professional Judgement and Decision-making Skills during Training.

Professional judgement and decision-making (PJDM) is an important skill for applied sport psychology (ASP) practitioners, because decisions made by the practitioner hold an influential role in the selection, design, and implementation of successful interventions (Martindale & Collins, 2005, 2010, 2012). For example, when assessing client needs, early decisions made by a practitioner on the nature of the goal (e.g., working to improve performance or well-being) will influence the type of relationship that a practitioner will elect to establish with a client (Martindale & Collins, 2005; Poczwardowski, Sherman, & Ravizza, 2004). Inevitably, these decisions influence how the practitioner applies sport psychology knowledge.

Although early decisions on the needs of the client are fundamental, there is a requirement within ASP practice for practitioners to continue to be adaptable to the dynamic and ill-structured environments in which they operate. In other words, ASP is largely a series of judgments and decisions (Martindale & Collins, 2012), and practitioners are required to make these judgements and decisions at multiple levels of practice (e.g., programme, intervention, and session) by responding to the changing needs of a client throughout the consulting process. For practitioners, professional educators, and supervisors these decision-making skills, along with the professional adaptability that is required to make them, should be a clear goal of professional training and development.

Previous training and development research in ASP has examined individual trainee accounts (e.g., McCormick, 2014), supervision (e.g., Andersen, Van Raalte, & Brewer, 1994), reflective practice (e.g., Knowles, Gilbourne, Tomlinson, & Anderson, 2007), and current learning experiences (e.g., McEwan & Tod, 2015). To understand how trainee sport
psychologists (TSPs) develop service-delivery competence (SDC), researchers (e.g., Hutter, Oldenhof-Veldman, Pijpers, & Oudejans, 2016; McEwan & Tod, 2015; Tod, Marchant, & Andersen, 2007) have identified the learning experiences that are useful for elements of professional development. For example, peer mentoring has been identified as an alternative form of guidance (e.g., in addition to supervision) whereby feedback could be sought on client cases. Research on TSP professional development continues to be useful for illuminating the helpful practices that TSPs can engage with throughout the professional training period. Nevertheless, to advance on these insights, there is scope to examine how these practices may contribute to the cognitive development of TSPs. For example, if peer mentoring offers guidance to a TSP, it may be beneficial for professional educators to understand what role peer guidance might play during the decision-making process (e.g., to what extent do TSPs draw on this peer guidance during their own client consultations? Do TSPs understand why it may be appropriate to apply this peer guidance in one client case, and not another? Does peer guidance help TSPs shape their mental representations of ASP practice? Or do TSPs rigidly copy and paste this peer guidance into their own repertoire of practice techniques without a critical and nuanced understanding of its application?).

The term macrocognition has been used when referring to the cognitive functions and processes that characterize how an individual may think in naturalistic settings (e.g., outside a laboratory setting, where conditions are dynamic; Crandall, Klein, & Hoffman, 2006). Traditionally, macrocognition research is focused on the study of the cognitive functions and processes that affect individuals who are faced with difficult scenarios, in time-pressured situations (e.g., firefighters or nurses; Klein, Calderwood, & Clinton-Cirocco, 2010; Patterson et al., 2016). The delivery of ASP services also has time-critical features. For example, in presenting a PJDM case study of a practitioner working with an elite judo player, Martindale and Collins (2012) demonstrated that although a practitioner will often have time to make
decisions analytically during the program and intervention level of practice (e.g., decisions about the direction of support provided), practitioners will also be required to respond almost immediately to the changing needs of a client, on a session-by-session level. Although it is clear the macrocognitive function of decision-making holds a fundamental role in ASP practice, what remains less clear, is how ASP practitioners develop the cognitive skills required to make these decisions in ill-structured and time-pressured client situations, along with the contextual sensitivity to recognize how and when to adapt their ASP knowledge during the decision-making process (Crandall et al., 2006).

To gain understanding of how decision-making expertise is acquired, researchers in other helping profession domains (e.g., nursing) have drawn comparisons between expert and novice practitioners. For example, in a review of the perceptual-cognitive skills required to make effective decisions, Klein and Hoffman (1993) noted that experts can perceive things that a novice may fail to identify. In other words, there are many things that an expert can perceive that remain invisible to others (e.g., an expert ASP practitioner may focus on the non-verbal cues of a client by observing how she interacts with others, whereas a novice might find this difficult due to inward attention, or dedication to pre-defined routines). Experience allows the expert to perceive when something is missing or when expectations have been violated. This cognitive expertise - whereby an individual can notice cues or recognize patterns, and can make perceptual discriminations - is one of the key cognitive elements that distinguishes experts from novices (Patterson et al., 2016). Thus, cognitive skills allow the practitioner to make sense of situations, to plan, to re-plan, and to make rapid decisions in time-pressured situations.

Drawing from empirical findings on expert and novice differences in learning strategies, Phillips, Klein, and Sieck (2004) present six goals that may be helpful for developing the cognitive skills required for effective decision-making: (a) enhance perceptual
skills (e.g., be able to detect typicality and variability in client cases), (b) enrich mental
models about the domain (e.g., know how their ‘tools’ work and recognize the limitations of
them), (c) construct a large and varied repertoire of patterns (e.g., develop situation
awareness to recognize relevant cues from clients), (d) provide a larger set of routines (e.g., a
range of skills and techniques that can be implemented with clients), (e) provide a larger
experience base of instances (e.g., a range of client experiences from which a TSP may draw
upon), and (f) encourage an attitude of responsibility for one’s own learning (e.g., a desire to
engage in professional development opportunities). Phillips et al. (2004) suggest that a
scenario-based instructional approach that addresses these six goals in training, may be
beneficial for facilitating the development of decision-making expertise within a specific
domain, such as ASP. For example, the use of case studies, where the practitioner is
couraged to review decisions made and draw lessons learned, might be helpful for
expanding the vicarious experience base and enriching the mental models from which they
may draw. Exploring how ASP practitioners develop the cognitive skills required for
effective decision-making may help to advance knowledge on how effectively current
practice addresses these six goals. The aim of this study, therefore, was explore how TSPs
develop decision-making expertise during their professional training qualification.

Method

Research Design

This study used an assorted analysis approach that combined an existing qualitative data set
(from previous doctoral studies) alongside the collection and analysis of a new qualitative
data set (the first author’s for current doctoral study; see Heaton, 2008 for more detail on
assorted analysis). The existing dataset used in this study was longitudinal, and involved 3
semi-structured interviews, exploring UK trainee sport psychologists’ development during
professional training. The aim of the existing dataset was to explore perceived change and
development as a result of learning during professional training. Participants engaged in semi-structured interviews to explore broad parameters of their development as TSPs, and discussions around the decision-making process that participants engaged with began to emerge. The current study aimed to add a ‘new conceptual focus’ (Heaton, 2008), by re-examining the existing dataset to distil new reflections on PJDM development. Through informal data sharing, the existing data set described above was made available by the second author and will now be referred to as data set A. For clarity, the steps associated with the assorted analysis approach used in this study are illustrated in Figure 1.

**Participants**

Following university ethical approval, all 11 UK trainee sport psychologist participants from data set A were contacted in relation to the re-analysis of their interview data for the new research objectives. Participants were informed of the purpose, risks and safeguards of this study. Seven (female, n = 1; and male, n = 6) of the 11 participants granted permission for their data to be re-analysed, and agreed to a follow-up interview with the **principal** author. Four of the 11 participants did not respond. All participants were enrolled on the British Psychological Society Qualification in Sport and Exercise Psychology (QSEP; Stage 2) at the time of the collection of data set A, and were either awaiting qualification or were eligible for registration as a Sport and Exercise Psychologist, recognised by the Health and Care Professions Council (HCPC) at the time of the follow-up interview.

**Procedures**

To be grounded in the context of training and development within the domain, the **principal** author became a member of the national training and development network for sport psychologists. Initially, this provided her with opportunities to listen to the training and development experiences of professional educators, supervisors, qualified practitioners, and
trainees. Exposure to this environment provided the building blocks for the principal author to familiarise herself with the vocabulary used by participants. The principal author was able to build relationships with the participants through informal discussions about their training experiences. Building rapport with the participants prior to the follow-up interview helped create researcher-participant familiarity and led to a richer discussion at the time of the follow-up interview.

After the analysis of data set A (described below) and before the follow-up interview, the principal author captured the training journey described in data set A for each participant by providing a written overview of our interpretation of their transcripts. This overview was sent to each participant to facilitate reflexive elaboration (Sparkes & Smith, 2014). Although none of the participants elaborated or added to what they had shared at previous interviews, the overview did create a discussion point for the start of each follow-up conversation.

**Interview guide.** The follow-up semi-structured interview guide was developed to explore areas of training specific to the development of practitioner PJDM expertise. For example, to understand how participants began to recognise a typical course of action, they were asked to “tell us about a significant experience that influenced a future client session.” The interview guide was designed based on the PJDM literature and themes that were developed from data set A. For example, participants from data set A referred to their supervisor on multiple occasions when they discussed how and why they worked with clients in particular ways. To ensure the research team understood the influence of the supervisor on the development of practitioner PJDM expertise, participants were asked to “tell us about the process of supervision during training.” To probe further, participants were asked to “describe a typical supervision meeting providing examples.” The principal author piloted the interview guide with the second author and a UK TSP. Interviews were conducted at the
participants’ convenience via Skype, telephone, or face-to-face. The interview guide is available from the principal author on request.

Data Analysis

Following the guidelines offered by Braun, Clarke, and Weate (2016), a reflexive thematic analysis (TA) was performed on data set A and B (generated from the follow-up interview) using a PJDM framework while drawing on the principles of abductive reasoning (e.g., while the principal author initially looked for evidence of development towards the six goals in training, she also made note of anything outside of the PJDM framework). TA allowed the principal author to search for patterns and develop themes which provided congruence with the aim of the study. The PJDM framework was initially designed based on the 6 goals of expertise offered by Phillips et al. (2004) and focused on how participants (1) enhanced their perceptual-cognitive skills, (2) enriched their mental models, (3) developed their repertoire of patterns, (4) developed a larger set of routines, (5) enhanced the meaningful experience base available to them, and (6) took responsibility for their own learning. The TA aimed to capture the ways in which participants might work towards achieving these goals in current training practice. For example, in data set A, participants recalled how they had begun to recognise how to help the client. To understand how participants developed perceptual-cognitive skills, the research team searched for training practices and processes that helped TSPs to recognise practice situations as typical and atypical.

All 28 transcripts (from dataset A & B combined) were transcribed verbatim, and read and re-read while listening to the audio recordings to check for accuracy. During data immersion, on-going discussions with the second author (who completed the semi-structured interviews in data set A) provided an opportunity to recover the contextual features from data.
set A that were not directly available to the principal author. These talks also provided an opportunity to glean insight into the rapport the second author and the participants had created during the collection of data set A (Szabo & Strang, 1997). Understanding the relationships between the second author and the participants helped the principal author to build on that rapport by referring to previous examples at each of the follow-up interviews. Initial codes were developed to represent aspects of the data relating to the development of PJDM expertise. For example, whenever a participant referred to ‘understanding how a consultation had developed into its current state’ the code ‘seeing consequences’ was allocated. A thematic map was created to assign each code to potential themes within the data sets. Themes and sub-themes were defined to capture the essence of what each theme represented in relation to the development of PJDM expertise. For example, the theme ‘learning and integrating new ideas’ was defined as how participants developed techniques that could be integrated into their own practice.

Research Credibility

Guided by the work of Sparkes and Smith (2014), several principles were identified to assist research credibility. The research team aimed to: (a) ensure we understood the training journey of each participant, (b) demonstrate to each participant that we cared about them, (c) uncover the perspectives we brought to the study, (d) capture participants’ perspectives on the development of their PJDM expertise, (e) provide accounts of PJDM training practice that would advance knowledge, and (f) provide information that is useful for practitioners and professional educators. Based on these guiding principles, and from a relativist position (see Smith & McGannon, 2018), rich rigour, credibility, sincerity, resonance, and significant contribution were built into our research steps. To ensure we adhered to these principles we: (a) created a data set that followed participants throughout their training journey; (b) built trust and rapport with each participant; (c) immersed ourselves in the participants’ training
environment; (d) employed principles of triangulation including analyst triangulation, member reflections, and audience review; (e) used critical friends to encourage self-reflexivity; (f) presented and discussed our findings within the field with other TSPs, qualified practitioners, supervisors, and professional educators; and (g) provided implications for TSP learning during training.

Analysis and Discussion

To illuminate that data analysis and interpretation took place in unison, the analysis and discussion are presented together, and this is congruent with how participants expressed their development towards the six goals proposed by Phillips et al. (2004); e.g., as participants gained experience, aspects from each of these goals developed at once leaving them difficult to separate. As a result of the TA, two themes and five sub-themes were developed and are supported by participant quotations. In presenting this information, we identified how the findings relate to and may extend understanding of how TSPs currently develop decision-making expertise during training.

Theme 1: Creating a Case Library from which to Draw

When participants described the initial development of PJDM skills, it stemmed from previous client experience. From each consultation, participants described a desire to understand why the client session had evolved in the way that it had. For example, “it’s…good to get an evaluation of the session, so what went well, why did it go well, what was it that I did that made it go so well…things that I need to remember…so you can use it again essentially” (TSP1). Participants suggested they wanted to learn from their experience to feed-forward to forthcoming client sessions, and previous experiences soon became the initial reference point for future decisions.
The role of practical experience in the quest for the development of expertise has been well researched over the years (e.g., Bjork, 2009; Davis, 2009; Ericsson, Krampe, & Tesch-Römer, 1993) and at times, has been identified as a means to achieving expert performance levels. Nevertheless, Klein and Hoffman (1993) and Ericsson et al. (1993) both suggest that direct experience alone, is insufficient. Instead, it is the opportunity to learn from experience, along with the degree of engagement with the task at hand, combined with the opportunity to be continually challenged that stimulates growth. This view is supported by TSP8 who described the benefit of reflecting on practice,

“I tend to go in [to a consultation] and react to situations. You do the reflections…pull apart the sessions…say what worked and didn’t work, why did I do that…where did it come from? … It’s the reflection afterwards…when you unpick, that helps you understand.”

Participants recognised that examining previous experience provided them with an opportunity to draw upon their experience with clients when deciding on how to move forward with new situations. This finding offers support to the claims by Cropley, Miles, Hanton, and Niven (2007) that reflecting on previous client experience can generate knowledge and self-awareness, and facilitated practitioner decision-making on how to improve future behaviour. Similar to the findings of McEwan and Tod (2015), participants in this study reported reflecting with their supervisors, with other practitioners (e.g., other TSPs), and individually (e.g., on their own without others) after client consultations.

Learning from experience, such as in the example above, has been increasingly linked to the development of perceptual-cognitive skills in a range of professions including medicine (e.g., Schubert, Denmark, Crandall, Grome, & Pappas, 2013), firefighting (e.g., Klein et al., 2010), and the military (e.g., Ross, Klein, Thunholm, Schmitt, & Baxter, 2004). Being able to
perceive and recognise what is important to derive from one situation to another has been identified as a significant step in the decision-making process. For example, Klein and Hoffman (1993) suggest that as perceptual-cognitive skills develop, we can expect an individual to begin to judge the typicality of a situation (e.g., a practitioner seeing what goals are feasible when deciding on how to proceed with a client), to see distinctions (e.g., a practitioner learning to discriminate between complex client issues), and to see antecedents and consequences (e.g., a practitioner visualising how a client situation has evolved into its current state, and how it may continue to develop).

**Analytical reasoning.** For participants in this study, examining previous experience was a means to engage in deliberate analytical reasoning, a process whereby practitioners participate in structured, systematic contemplation of practice features, and how they relate to judgement of client cases (Patterson et al., 2016). TSP2 exemplified this process,

“...I’ll have the consultations...and I’ll...start to write reflections of ...the situation...what I thought went really well and maybe...action planning for next time...At that point I might keep my reflections pretty brief...and then I’ll come back to them...I’ll start...an afternoon of research ...to find something out...like... 'how can I add to this' ...it could be an answer that I’m looking for...That then starts a process of me going out there and doing a bit of research, ...and reading some books.”

Until recently, little was understood about the nature of the environment in which an ASP practitioner is required to make decisions. Nevertheless, in establishing theoretical understanding on the development of PJDM expertise within ASP, Martindale and Collins (2013) offered new insights on why the development of analytical reasoning may be of benefit to the decision-making process in which an applied practitioner will engage. For example, in the presentation of a PJDM case study of a practitioner working with an elite
judo athlete, Martindale and Collins (2012) highlighted the influence of practitioner PJDM at multiple levels of practice including programme (e.g., anticipating how the theoretical orientation will fit with the overall program of support), intervention (e.g., considering how the direction of support will fit the design of the specific intervention) and session level (responding to emerging moment-to-moment issues within a session). The authors emphasized the role of analytical reasoning in both the programme and intervention level of practice, where the practitioner had a considerable amount of time available to engage in the decision-making process.

The development of analytical reasoning in the present study was facilitated through the examination of previous experience (See Huntley, Cropley, Gilbourne, Sparkes, & Knowles, 2014 for a review of reflective practice in sport), by consulting contemporary literature, or engaging in discussion with peers or supervisors. For example, TSP1 noted the benefit of discussing upcoming client sessions with a professional practice group, “[It’s] really useful and that tends to be more for the trainees so ‘I’ve got this [client session] upcoming and what is everyone’s ideas and opinions?’” Engaging in analytical reasoning during training provided participants with an opportunity to consider different options that could be applied to client cases, while evaluating an alternative course of action (from what they had originally planned), individually or with peers and supervisors. Training, as illustrated by the examples provided above, where the action is slow and allows participants time to process information, may be of benefit for developing the analytical aspect of reasoning that is necessary in ASP decision-making (Martindale & Collins, 2013).

**Situation awareness.** Experience slowly became a catalyst for participants to recognise client situations. For example, TSP7 reflected on how he had developed with more experience,
“I’ve probably got a better sense of the decision making actually. I’ve got a better
sense of…if I do action X now, then Y results, and I’ve got a better sense of well that
will also result in Z and I don’t want Z, I'd rather have W so what I’ll do is this.”

By drawing on previous client experience, participants could recognise similar
situations to help them identify a typical course of action that could be used with a client.
According to Klein and Hoffman (1993), developing a sense of typicality, as in the example
described above, can help an individual to better identify what information is important to
derive from a situation. Participants were essentially pattern matching against what they had
already seen or done. Being able to see patterns provides an individual with an opportunity to
develop situation awareness, helping them to recognise relevant cues within the environment
(Klein, 2017). This awareness can help facilitate practitioners in using the macrocognitive
process of mental simulation that supports the primary functions of decision-making, sense-
making, and problem detection (Crandall et al., 2006). Mental simulation requires the
practitioner to enact a series of events, and assess them as they lead to possible outcomes
while anticipating difficulties (Klein, Moon, & Hoffman, 2006). For example, the participant
quotation above is exemplifying a variation of the recognition-primed decision model,
presented by Klein (2017). Here, the participant is evaluating option ‘X’ by imagining how
this course of action may play out with the client (e.g., ‘Y’ and possibly ‘Z’). The participant
anticipates problems with option ‘X’, and rejects this in favour of option ‘W’ as the
anticipated end result. Being able to mentally simulate a course of action is derived from
extensive experience where mental models are formed to develop cognitive frameworks that
are immediately available to give meaning and structure to familiar situations (Hoffman et al.,
2014).

While mental simulation is commonly associated with making decisions at speed
(Klein & Crandall, 1995), participants in this study continued to develop and engage in this
macrocognitive process in an analytical manner. For example, TSP8 reflected on his approach to decision-making,

“…I’d…do the reading on it [client situation] and chat to other colleagues and peers that I’ve got… maybe even look back at other stuff that I’ve done before and see if there was any similarities or maybe another athlete has shown something similar…-

So how did that help them? And then decide the best way to move forward with that.”

Although analytical reasoning may be useful for making judgements and decisions at the programme or intervention stage of practice, it might not fully prepare a practitioner with the skills required to make effective decisions at a session level where the practitioner is expected to respond at speed, intuitively.

Vicarious experience. Participants also referred to the experiences of other practitioners as a source they could draw upon when making decisions. This experience included reading, observing, and listening to the client experiences of others. For example, when referring to a discussion with another practitioner, TSP7 noted,

“Now that I reflect on it, a lot of listening to other psychs [psychologists]; it’s storytelling, and hearing their stories…Maybe the massively experienced psych of 40 years has…got a lot of stories, cause they’ve seen a lot of stuff…I think that’s very valuable for trainees to hear those stories.”

When asked what he found useful about this experience, TSP7 continued:

I guess a part of it is hearing what the approach was, how did they go about it? …how did it [the presenting issue] come to be there in the first place? …but also…what approach did you use? …What did the client do? How did they respond? And it’s…like you get 20 sessions condensed into 2 minutes versus, you had to sit there for 6 months…So you…get that compression of knowledge.
The merits of sharing experienced practitioners’ accounts of practice with trainee practitioners has been well-documented in other domains such as the military (Klein, Hintze, & Saab, 2013), healthcare (Geis et al., 2018), and firefighting (Hintze, 2008). Often, when the shared experience is vivid enough, it can add to the experience base that a practitioner may draw upon when making decisions. For example, using principles of cognitive task analysis (see Crandall et al., 2006 for a review), Hintze (2008) developed scenario-based training to allow novice firefighters to experience the situations through the eyes of expert firefighters. Hintze (2008) found that scenario-based training, where expert feedback was made available, was helpful for expanding the experience base of novice firefighters, with improvements in situation awareness and decision-making skills.

The sharing of experience was evident throughout participants’ training, and was used during supervision, peer discussions, and networking events. Although identified as a helpful experience that often stimulated the microcognitive process of storybuilding (Crandall et al., 2006), participants noted it could be unhelpful at times too. For example, TSP10 claimed, “He’s [his supervisor] brilliant but he’ll go off on a tangent. Sometimes the meetings can end up talking about one of his clients. Now he’s doing it in a sense that I’ll share my experience and how I’m thinking about it, but sometimes…I don’t know what the point is here.”

Participants claimed at times they failed to understand the importance of the experienced being shared, missing the critical cues they might learn from, and subsequently, were confused by the point of the scenario. For example, TSP7 described storybuilding during supervision:

“The [supervision] sessions were so informal but I guess those stories are…a constant. You’re always gonna get stories both ways [from supervisor and trainee] but it’s how
they tell that story that will often cause a reaction…your tone of voice just changed,
and sometimes that can be all you need to see something is important here.”

Although confusing, on occasion participants could pinpoint important cues within the
scenario by how it was told (e.g., a change in tone). Although this strategy might be helpful
for alerting the practitioner to ‘something’ important, unless the practitioner can understand
and make sense of the situation, then the sharing of experience during training may not be
sufficient to act as a vicarious experience where the practitioner can use the presenting
information in an effective way in future client sessions (Klein, 2017).

Theme 2: Developing a Repertoire of Techniques

As participants developed mental models of how psychological skills and techniques
were supposed to work in practice, they began to shape their role as sport psychologists, and
practice was often changed to reflect these developments. For example, TSP4 reflected on
how he practiced in year 1 of training: “I was so focused on getting through those questions
[from a book] that I wasn’t listening properly, I was taking them [the client] to
places…they…had no interest in going. I was forcing them in directions…” When asked
how he practiced now, TSP4 responded: “It’s client-centred…I’m quite passionate about
getting…to that root cause.” Participants agreed that in the early stages of training, they were
more likely to apply and stick to a ‘recipe-like’ approach – lifting guidelines for practice from
a book, and applying each step in a structured manner. This finding reflects the work of Tod,
Andersen, and Marchant (2009) who found that TSPs adopt an external and rigid orientation
within their role during training. This practice approach may be a direct result of the
professional pressures initially placed upon the trainee practitioner to demonstrate
competency in areas outlined by professional bodies, and may help to explain why
participants were reluctant to deviate from their initial plan and the decisions embedded within it, in the early stages of training.

As participants progressed through training, the accumulation of a range of experiences played a role in the development of practice models, and how skills and techniques embedded within practice could be used with clients. Participants frequently noted a change in their understanding of ‘how things worked’ and began to make changes. For example, TSP5 reflected on how his understanding of listening skills was beginning to change:

“I’m thinking…I’ve got to listen - not just hearing what they’re saying but focusing on what they are saying…I’ve found myself thinking what question am I going to ask now and how does it fit in with my approach…before I’ve really finished listening to what they are saying.”

Participants agreed that their understanding of ‘how things worked’ developed through learning from their own experience with clients, and by listening to or reading about the experiences of others. For example, TSP5 described the changes he was making to his practice: “I've read a book on counselling skills…learning about active listening, learning about paraphrasing, summarising. But of course it's not just a series of techniques, it's more the attitudes they reflect…” This cognitive representation of ‘how things work’ is often referred to as a mental model - an internal representation of the external world. In cognitive science, these mental representations are a focus of how individuals understand systems (Rouse & Morris, 1986). They allow the decision-maker to describe, explain, and predict the purpose, form and function of practice skills and techniques. For example, as a mental model of ‘listening to the client’ develops, we can expect a practitioner to be able to describe the purpose and form of listening (i.e., why listening skills exist, and what they look like in
practice), explain the function and state of listening skills (i.e., how listening to the client works, and what this will achieve with a client), and predict the state of listening (i.e., foreseeing how this may influence the client session). In developing mental models of their domain, participants began to create a set of skills and techniques they could draw upon when working with clients.

Learning and elaborating on new ideas. Being exposed to skills, techniques, and approaches used by other practitioners was identified by participants as an opportunity to borrow and adapt ideas for their own practice. For example, TSP7 noted;

“I steal stuff…I stole one [an ice-breaker] from an Institute psych[ologist] that I use all the time. It’s great but I met up with another trainee…a few months ago, and he said, ‘oh I always do this’ - …he was talking about decision-making under pressure, he’s got this little game he plays and I was like oh that’s brilliant.”

Participants often used skills and techniques that had worked for other practitioners and adapted them in a similar context within their own practice. This shows similarities to earlier discussions on situations becoming familiar, in that participants may be developing an ability to recognise client situations as either typical or atypical, and draw upon the action they have associated with this situation (Klein, 2017).

Although limited during the training period, formal observation (i.e., one-to-one organised observation) was a training practice that prompted participants to think about why and how they could begin to adapt their own practice. For example, when discussing observation, TSP1 noted,

“…one observation that I did of someone delivering a one-to-one…she was very comfortable with silence and didn’t…feel the need to jump in…and say something, and…what often happened was she’d long that silence out, and the athlete would break
it...cause he just had some time to think. I remember taking that from that session and thinking...that's something that I need to become more comfortable with - riding out the silence and giving the athlete time to think... There were loads of strategies, techniques that you pick up and just seeing it...reinforced that it might be something that I want to consider in my practice.”

Participants believed that formal observation made them think about their own practice, and how they could develop it to become better practitioners. Examining experience post-observation continued to provide participants with an opportunity to challenge their thinking about why things worked for others, before implementing change in their own practice. Modelling of performance, as in the example above, has been increasingly linked to the development of perceptual-cognitive skills when observation acts as a prompt for learning to occur (Klein & Hoffman, 1993). Despite what has been learnt from social psychologists (i.e., people learn from watching the behaviour of others), formal observation opportunities within ASP training were limited.

Have I become my supervisor? As participants reflected on how they developed their practice, it became apparent that informal observation had also played a role. For example, TSP7 noted:

“...I think questioning skills - I think that’s one thing [from a supervision meeting] I’ve always picked up informally from [my supervisor], the other thing is...listening skills...I picked up quite a lot of that from him informally...Looking for entry points and listening and reflecting back. These are basic day one skills and just observing how well he does that, you’re like ‘right ok I’ve got a long way to go.’ ”
Participants commented that they had integrated various skills and techniques from supervision, and now adopted a similar approach to practice when deciding on how to work with clients.

For example, TSP10 explained, “I feel through reflection that I… just embodied [his supervisor], and his attitudes, and styles and mannerisms, not mannerisms per se but the way he speaks, and his ideas and that makes me cringe.” Participants in this study, who all had the same philosophical perspective as their supervisor, agreed that supervisors were helping in a similar way in which we would expect them to work with clients. This finding offers support to the ethical concerns outlined by Castillo (2014) in that models of supervision tend to mirror models of therapy. Castillo outlines various other concerns with the supervisory-trainee relationship including transference. Similar to Van Raalte and Andersen (2000), Castillo suggests that due to the power and knowledge differential inherent in the supervisory relationship, it is entirely possible that a trainee practitioner may begin to mimic a past significant relationship (e.g., parent or coach). This transference could lead the trainee practitioner to relate to his or her supervisor with the aim of gaining approval or recognition.

Findings from this study may offer support to these claims by Castillo as TSP10 reflected on why he adopted a similar approach to his supervisor: “So I never felt I had to, it was just…what age was I? 22 - quite impressionable, still am... It’s easy then to take on the beliefs of someone, I suppose in a sense you admired because of their different approach.” In the early stages of training, TSPs professional identities may reflect those of their supervisors. With critical reflection on their own values and worldviews, TSPs might begin to develop their own approach to practice (Tod, Hutter, & Eubank, 2017).

The idea that supervisors hold a significant role in the development of practice models, and subsequently, philosophies of practice, echoes research findings on supervision
in sport psychology and teacher training (e.g., Van Raalte & Andersen, 2000; Walkington, 2005). For example, in a study where teacher supervisors were encouraged to think about how the values and beliefs of trainee teachers influenced the dynamics of learning to teach, Walkington (2005) emphasized the role supervisors hold in the development of a philosophy of practice, and suggested that supervisors must continually encourage trainee practitioners to challenge their experiences and beliefs. Without the opportunity to do this, trainee practitioners will simply maintain the beliefs and behaviours of the supervisor. Findings from this study may offer support to the claims by Walkington. For example, while reflecting on the development of his professional philosophy, TSP10 noted that although he was always encouraged to do his own reading and generate his own ideas for practice, he commented that his supervisor still held an influencing role:

“So massive influence on it [his philosophy of practice]…when I look back to make it more specific to my own experience [of training]…I’m like, where am I developing though? [his supervisor], (1), you’re not giving me anything else to read, and (2), I shouldn’t be expecting you to do that anyway because if you do give me anything it’s all influenced by existential approaches. It’s almost like, I just want something else. Something different.”

TSP10 continued to reflect on his approach to training and practice:

“I don’t know if you’ve came across Brene Brown on Vulnerability? …I find it a fascinating area, but for me I’m always looking at it from an existential perspective… So it’s kind of annoying because Brene Brown didn’t write it in that context so why am I then looking at it like that?”

These findings support Hutter (2014), who outlined ethical concerns for novice supervisors on whether they were examining their own work when monitoring trainee progress. For
example, Hutter noted that the supervisor will advise and guide TSPs in their work with clients. TSPs then absorb the supervisor’s input, and (at least parts of) the input is worked into their own practice. Thus, a case can be made for the influence that supervisors have on TSPs in relation to professional behaviour. Although TSPs may find this imitation helpful in the early stages of training where they strive to demonstrate competence, TSPs may fall short when forced to make decisions in atypical client situations. In short, unless TSPs understand the rationale behind their behaviour, ASP as a profession is in danger of producing practitioners who know how to fit the context, but lack the skills and confidence required to make effective decisions in new or unfamiliar situations.

Applied Implications

The current study has contributed to the literature on sport psychology training by providing empirical data on UK TSPs’ perspectives on developing decision-making expertise during training. Findings indicate that opportunities exist to accelerate development of these cognitive skills (e.g., ensuring that TSPs have a critical and nuanced understanding of why skills and techniques were appropriate for application in one client case, and not another).

The current findings give rise to several applied implications. First, a recurrent finding in the study was the development of analytical reasoning to inform decision-making. TSPs frequently created practice opportunities that provided time to process information by examining previous experience, by consulting contemporary literature, and through discussions with peers and supervisors. For example, TSPs drew upon their previous experience with clients to look for similarities across client cases while searching for direction on how to move forward when selecting appropriate interventions for new client situations. TSPs also noted value in discussing client situations with peers where they could collaboratively explore and identify ways to move forward in future client situations.
Although this practice is helpful for making decisions at the programme or intervention level of practice (Martindale & Collins, 2013), it may not fully prepare TSPs to make decisions at a session level where the practitioner must respond to the changing needs of a client, at speed. When a practitioner can see consequences at speed, it becomes a source of power (Klein, 2017). In the expertise literature, this source of power is often in the form of a mental simulation, allowing the practitioner to explain cues and information they have received to interpret and diagnose a situation at speed (Klein, 2017; Klein & Hoffman, 1993).

Given that ASP practitioners are required to think both analytically and intuitively when applying sport psychology knowledge (Martindale & Collins, 2013), and with findings from this study suggesting that TSPs are more attentive to developing analytical reasoning, it may be beneficial for professional educators and supervisors to introduce training practices that require the TSP to apply mental simulation (e.g., in role-play) to a client situation where they can respond to the anticipated end states, at speed.

Tod et al. (2007) have documented the value in gaining service-delivery experience via role-plays. Role-plays were useful for practicing how to manage specific situations that may arise with clients, while drawing on past experiences, as practitioners performed within a replicated client experience. Building on the work of Tod et al., role-play practice that prompts TSPs to use mental simulation (e.g., to enact a series of events) where they pattern match from previous experience may be useful for fuelling the development of the intuitive type of thinking required in ASP decision-making. The model of mental simulation proposed by Klein (2017) can guide this practice. Applying mental simulation during role-play would require the TSP to first identify the need (e.g., to explain the past, or project the future of a client situation). The TSP would then develop a 6-phase action sequence (e.g., the set of transitions that make up the simulation), before evaluating the sequence for coherence (e.g., does it make sense?), applicability (e.g., will the TSP get what they need?), and completeness.
(e.g., does it include enough detail?). The sequence is then run to form an explanation, model, or projection. If the TSP experiences difficulties with the internal evaluation, the TSP may re-examine the need, and/or reconstruct the sequence before trying again.

Role-play with mental simulation could also strengthen the development of intuition. For example, in clinical and counselling psychology, role-plays were identified as useful for developing service-delivery knowledge through peer, actor, and supervisor feedback (McEwan & Tod, 2015). Although Tod et al. (2007) reported that students felt uncomfortable and fearful of their behaviour being identified as right or wrong during role-play, engaging in critical discussions on decisions made during mental simulation might help to strengthen the experience base that TSPs can draw from in future consultations. Pitt et al. (2015) have also outlined the benefits of immediate, real-time feedback for TSPs who work in consultancy teams, including opportunities to draw upon a greater depth of experience when interpreting client situations, and to enhance TSP expertise in consultancy settings. Martindale and Collins (2013) noted that opportunities to engage in pro-longed practice in combination with real-time feedback is considered one of the conditions for the development of skilled intuition in ASP. For example, if a TSP applies sport psychology knowledge that is less helpful for a client, and remains unaware of this, it is likely that the TSP will reproduce this behaviour from memory, creating a faulty intuition. The introduction of training practice that also allows for real-time feedback, may create an opportunity to refocus aspects of training on why we do the things that we do, creating more meaningful learning experiences for the TSP (Martindale & Collins, 2010). This blended approach may be useful for fuelling development of both the analytical and intuitive thinking that is a requirement of ASP decision-making.

Findings also indicated ways in which the experiences of other practitioners (e.g., supervisors) could be optimised for use in sport psychology training. TSPs emphasised drawing upon the experiences of others when deciding how to move forward during
consultations, and when to develop and refine their practice models. Although the sharing of scenarios from supervisor to trainee has been identified as a means to pattern match from case-to-case in other domains (Patterson et al., 2016), trainees must first understand the scenario being staged to use the presenting information in a meaningful way in future client cases (Crandall et al., 2006). For example, TSPs in this study reported missing critical cues they might learn from within a scenario (e.g., supervisor’s shared experience), and at times were left confused. Nevertheless, TSPs noted that on occasion, even if they failed to understand, they could still pinpoint important parts of the story by a change in tone. Although this shared experience might be helpful in the short term, unless TSPs can make sense of the scenario being presented, and the decision-making process embedded within it (e.g., what information was considered during decision-making?), it is unlikely to be helpful in applied situations in the future (Klein, 2017). In other words, it would be naïve to assume that TSPs could borrow and apply the work of other practitioners with the same effect, unless they understand the rationale for the application (i.e., why do they do the things that they do?; Martindale & Collins, 2010). One way that TSPs may gain access to this rationale, is to elicit the decision-making knowledge used by domain experts (e.g., ASP supervisors) via cognitive apprenticeship.

Cognitive apprenticeship is a model of training that helps to make thinking visible by illuminating the cognitive strategies used to make decisions (Collins, Brown, & Holum, 1991). In contrast to traditional apprenticeship models, where the expert (e.g., the supervisor) shows the trainee how to complete a task, cognitive apprenticeship provides a platform to elicit how the expert thinks, what they are paying attention to, how they structure information, and the strategies they are using to make decisions or detect problems (Crandall & Gamblian, 1991). These knowledge elicitation principles have been applied in various domains, and in various forms, to capture and disseminate the tacit knowledge used during
expert decision-making. For example, Crandall and Gamblian (1991) used the critical decision method (CDM) to capture and communicate the perceptual skills needed by nurses who were new to a neonatal ward. Patterson et al. (2016) also used the CDM to develop simulation-based training that would facilitate the acquisition of expertise in the early recognition of sepsis. Using applied cognitive task analysis (ACTA), Martindale, Collins, and Morton (2017) ‘made thinking visible’ by capturing the decision-making thought processes of expert crime scene examiners, while highlighting the cognitive demands placed upon these practitioners when working in an ill-defined domain. In these studies, the tacit knowledge required for expert decision-making was extracted and used to develop training material to bring new practitioners up to speed. In ASP, ACTA could be applied to maximise the use of shared experience between the supervisor and their TSPs. ACTA consists of three interview techniques with the expert (e.g., the supervisor) to extract the cognitive demands of the experience they are sharing (Militello & Hutton, 1998). The final step in ACTA is to produce a cognitive demands table to consolidate the data collected during each interview technique. This data could then be used to create training scenarios for TSPs where they can compare their thinking (e.g., cues, projections, and anomalies) in simulated client cases, to that of the expert.

Findings from the current study offer support to Martindale and Collins (2010) suggestion that there are several benefits to exploring the metacognition behind expert decision-making including uncovering another layer of understanding when disseminating knowledge to the TSP. For example, instead of only explaining what the supervisor did, it may be helpful for the trainee to hear why they recognised cues as relevant to that client situation, what they anticipated would happen, or why some goals were more feasible than others (Klein & Hoffman, 1993). Exposure to this type of information during training could encourage a step away from traditional procedural training approaches (e.g., a copy and paste
approach as discussed earlier in this study) by helping trainees to recognise different options that may be available to them, and why these options might be applicable in some client situations and not others (Cruickshank, Martindale, & Collins, 2018). The application of knowledge elicitation studies in ASP that focus specifically on decision-making have the potential to produce training material that could fuel development of TSPs’ ability to make effective decisions in a complex and ill-structured domain, such as ASP.

Finally, given that supervisors have been identified to influence how TSPs make decisions, it may be helpful to uncover the supervisors’ perspective on the role they play in developing TSP decision-making expertise during professional training. For example, TSPs noted they unconsciously picked up skills and techniques that could be used with clients by informally observing supervisors. Subsequently, practice models often mirrored the approach adopted by the supervisor. Informal observation, where the TSP remains unchallenged on why supervisors might be practicing in the way that they do, may limit the development of key microcognitive functions and processes such as decision-making, sensemaking, storybuilding, and problem detection. Therefore, it may be beneficial to explore the intentions of training practices offered by supervisors (e.g., observation), during supervision. This line of enquiry may help to illuminate new training requirements for both TSPs and supervisors, while providing new training direction for professional training educators (Cruickshank et al., 2018).

Reviewer 1 & 2:

Response

Thank you for the helpful comments, and for taking the time to re-read this manuscript. It really has helped to strengthen the contribution.

Associate Editor:

Response

Many thanks for your kind words regarding the revision, and again, for taking the time to re-read this manuscript. Please find below a response to each of your points.
