S17 A PILOT STUDY OF THE PREVALENCE OF SLEEP DISORDERED BREATHING (SDB) AND NOCTURNAL HYPOXIA IN SYMPTOMATIC ADULTS WITH SICKLE CELL DISEASE (SCD) AND ITS RELATIONSHIP WITH DISEASE SEVERITY

doi:10.1136/thx.2010.150912.17

Introduction There are few effective therapies available for the long-term management of the cardiac and renal sequelae of SCD. Identifying reversible factors, which exacerbate disease severity, would facilitate development of new therapies or novel applications of established treatments. Nocturnal hypoxia (NH) merits investigation as a disease modulating factor as it is established that hypoxia promotes polymerisation of sickle haemoglobin and this is reversible with oxygen therapy (Noguchi et al, 1993). Although NH is common in children with SCD and is associated with poor outcome, similar data for adults with SCD are lacking. This is the first study to determine the prevalence of OSA and NH and quantify the severity of NH in adults with SCD. In addition, we investigated the correlation between the degree of NH and organ dysfunction.

Method Patients attending SCD clinic had an Epworth sleepiness score performed. Patients with either an ESS ≥10 or symptoms suggestive of SDB were offered nocturnal oximetry. Nocturnal oximetry findings were objectively scored and compared with the detailed clinical datasets collected at regular clinic attendances. OSA was defined as 4% oxygen desaturation index (4% ODI) of >10 events/h and NH was defined as ≥30% total sleep time (TST) with SpO2 <90%.

Results 93 patients were screened. 34 had ESS ≥10 or clinical symptoms suggestive of SDB. 22 underwent nocturnal oximetry; 93 patients were screened. 34 had ESS ≥10 or symptoms suggestive of SDB. 22 underwent nocturnal oximetry; 22 underwent nocturnal oximetry; 22 underwent nocturnal oximetry; 22 underwent nocturnal oximetry; 22 underwent nocturnal oximetry. Nocturnal oximetry findings were objectively scored and compared with the detailed clinical datasets collected at regular clinic attendances. OSA was defined as 4% oxygen desaturation index (4% ODI) of >10 events/h and NH was defined as ≥30% total sleep time (TST) with SpO2 <90%.

Results 93 patients were screened. 34 had ESS ≥10 or symptoms suggestive of SDB. 22 underwent nocturnal oximetry.

Conclusion This small pilot study showed that OSA and NH had a prevalence of 59% in symptomatic adult SCD patients. These data have demonstrated a correlation between the severity of nocturnal hypoxia and pulmonary hypertension, renal impairment and priapism. These observations have not previously been reported. The strength of these correlations could suggest a causal relationship, although this needs to be confirmed in a larger prospective trial. Future studies should investigate the relationship between OSA, nocturnal hypoxia and organ dysfunction and need to be focussed on interventions such as nocturnal oxygen and continuous positive airway pressure.

New assessments in cystic fibrosis

S18 LONGITUDINAL ASSESSMENT OF BIOMARKERS FOR CLINICAL TRIALS OF NOVEL THERAPEUTIC AGENTS: THE RUN-IN STUDY

doi:10.1136/thx.2010.150912.18

1E W F W Alton, 2C Boyd, 3C Cunningham, 1J C Davies, 4S C Hyde, 2J A Innes, 4D R Gill, 1A Greening, 1U Griersonbach, 1T Higgins, 4J J Porteous. 1Department of Gene Therapy, Imperial College, London, UK; 2Western General Hospital, Edinburgh, UK; 3The Royal Hospital for Sick Children, Edinburgh, UK; 4Gene Medicine Research Group, Oxford University, Oxford, UK

We will be undertaking a phase IIB clinical trial of repeated application of lipid-based gene therapy over a one year period in approximately 100 CF patients (Multidose Trial). In preparation for this, we sought to address two key questions. Firstly, could we define the optimal set of patients in which the therapy could both be delivered (good access to the airways via nebulisation), and in whom any therapeutic effect was measurable (one or more abnormal measures of lung disease). Secondly, in this set of ‘can deliver—can measure’ patients, which biomarker(s) could be powered to be the primary outcome measure for the trial. To address both questions, we undertook a study (Run-in), cross-sectionally assessing ‘can deliver’ and longitudinally assessing a large set of candidate biomarkers for ‘can measure’.

142 patients were enrolled at two clinical centres; 154 of these remained in the study after four visits spaced at approximately 4–5 month intervals. Biomarkers assessed cross-sectionally included radionucleotide deposition scans, CT and mucociliary clearance. Longitudinal biomarkers included a large series of serum, sputum and exhaled breath inflammatory markers, lung physiology, exercise-related assays and quality of life assessment. 12 patients were judged too severe for adequate delivery and were excluded. A shortlist of 4 biomarkers was generated based on a) showing a CF/non-CF difference, b) response to course of intravenous antibiotics, and c) coefficients of variation. These four were matched against the remaining 142 patients, and a further seven patients excluded in whom none of these short listed biomarkers was abnormal. 89 patients (3 or 4 biomarkers abnormal) have been definitely included to progress into the Multidose Trial, and a further 46 (1 or 2 biomarkers abnormal) are awaiting the final primary outcome selection. The Run-in study has, therefore, been able to a) select a cohort of ‘optimal’ patients in which to assess gene therapy and b) provide an indication of which may be the most useful biomarkers to use in phase IIB clinical trials of novel therapeutic agents.

S19 REAL TIME PCR IN THE IDENTIFICATION AND MANAGEMENT OF ASPERGILLUS IN CF

doi:10.1136/thx.2010.150912.19

1C G Baxter, 2A M Jones, 3A K Webb, 4D W Denning. 1University Hospital of South Manchester, Education and Research Department, Manchester, UK; 2Manchester Adult CF Unit, Manchester, UK

Purpose The reported prevalence of Aspergillus fumigatus in CF sputum varies widely from 12 to 57%. While patients with ABPA are routinely treated with antifungals, it is not known whether colonised
