Abstract

First evidence of the $B^0 \rightarrow J/\psi \omega$ decay is found and the $B^0_s \rightarrow J/\psi \eta$ and $B^0_s \rightarrow J/\psi \eta'$ decays are studied using a dataset corresponding to an integrated luminosity of $1.0 \text{fb}^{-1}$ collected by the LHCb experiment in proton–proton collisions at a centre-of-mass energy of $\sqrt{s} = 7 \text{TeV}$. The branching fractions of these decays are measured relative to that of the $B^0 \rightarrow J/\psi \rho^0$ decay:

$$\frac{\mathcal{B}(B^0 \rightarrow J/\psi \omega)}{\mathcal{B}(B^0 \rightarrow J/\psi \rho^0)} = 0.89 \pm 0.19(\text{stat})^{+0.07}_{-0.13}(\text{syst}),$$

$$\frac{\mathcal{B}(B^0_s \rightarrow J/\psi \eta)}{\mathcal{B}(B^0 \rightarrow J/\psi \rho^0)} = 14.0 \pm 1.2(\text{stat})^{+1.1}_{-1.5}(\text{syst})^{+1.1}_{-1.0}\left(\frac{f_d}{f_s}\right),$$

$$\frac{\mathcal{B}(B^0_s \rightarrow J/\psi \eta')}{\mathcal{B}(B^0 \rightarrow J/\psi \rho^0)} = 12.7 \pm 1.1(\text{stat})^{+0.5}_{-1.3}(\text{syst})^{+1.0}_{-0.9}\left(\frac{f_d}{f_s}\right),$$

where the last uncertainty is due to the knowledge of $f_d/f_s$, the ratio of b-quark hadronization factors that accounts for the different production rate of $B^0$ and $B^0_s$ mesons. The ratio of the branching fractions of $B^0_s \rightarrow J/\psi \eta'$ and $B^0_s \rightarrow J/\psi \eta$ decays is measured to be

$$\frac{\mathcal{B}(B^0_s \rightarrow J/\psi \eta')}{\mathcal{B}(B^0_s \rightarrow J/\psi \eta)} = 0.90 \pm 0.09(\text{stat})^{+0.06}_{-0.02}(\text{syst}).$$

1. Introduction

Decays of B mesons into a $J/\psi$ and a light meson are dominated by color-suppressed tree diagrams involving $\bar{b} \to \bar{c}c\bar{s}$ and $\bar{b} \to \bar{c}c\bar{d}$ transitions (see Fig. 1). Contributions from other diagrams are expected to be small [1]. Measurements of the branching fractions of these decays can help to shed light on hadronic interactions. The decay $B^0 \to J/\psi\omega$ has not been observed previously. The CLEO Collaboration has set the most restrictive upper limit to date of $B(B^0 \to J/\psi\omega) < 2.7 \times 10^{-4}$ at 90% confidence level [2].

The $B^0_s \to J/\psi\eta$ decays were observed by the Belle Collaboration [3] with branching fractions $B(B^0_s \to J/\psi\eta) = (5.10 \pm 0.50 \pm 0.25^{+1.14}_{-0.79}) \times 10^{-4}$ and $B(B^0_s \to J/\psi\eta') = (3.71 \pm 0.61 \pm 0.18^{+0.83}_{-0.57}) \times 10^{-4}$, where the first uncertainty is statistical, the second is systematic and the third one is due to an uncertainty of the number of produced $B^0_s\bar{B}^0_s$ pairs. Since both final states are $CP$ eigenstates, time-dependent $CP$ violation studies and access to the $B^0_s\bar{B}^0_s$ mixing phase $\phi_s$ will be possible in the future [4,5]. The theoretical prediction for these branching fractions and their ratio relies on knowledge of the $\eta-\eta'$ mixing phase $\phi_P$. Taking $\phi_P = (41.4 \pm 0.5)^\circ$ [6] and ignoring a possible gluonic component and corrections due to form factors, the ratio becomes

$$\frac{B(B^0_s \to J/\psi\eta)}{B(B^0_s \to J/\psi\eta')} \times \frac{F_{\eta}^s}{F_{\eta'}^s} = \frac{1}{\tan^2\phi_P} = 1.28^{+0.10}_{-0.08}. $$

Here $F_{\eta}^{(s)}$ is the phase space factor of the $B_s^0 \to J/\psi\eta^{(s)}$ decay and the uncertainty is due to the inaccuracy in the knowledge of the mixing phase. As discussed in Ref. [1], a precise measurement of this ratio tests $SU(3)$ flavour symmetry. In addition, in combination with other measurements, the fraction of the gluonic component in the $\eta'$ meson can eventually be estimated [7].

The analysis presented here is based on a data sample corresponding to an integrated luminosity of 1.0 fb$^{-1}$ collected by the LHCb detector in 2011 in pp collisions at a centre-of-mass energy of $\sqrt{s} = 7$ TeV. The branching fractions of these decays are measured relative to $B(B^0 \to J/\psi\rho^0)$ and the ratio $\frac{B(B^0 \to J/\psi\rho^0)}{B(B^0 \to J/\psi\eta)}$ is determined.

2. LHCb detector

The LHCb detector [8] is a single-arm forward spectrometer covering the pseudorapidity range $2 < \eta < 5$, designed for the study of $b$- and $c$-hadrons. The detector includes a high precision tracking system consisting of a silicon-strip vertex detector surrounding the pp interaction region, a large-area silicon-strip detector located upstream of a dipole magnet with a bending power of about 4 Tm, and three stations of silicon-strip detectors and straw drift tubes placed...
downstream. The combined tracking system has a momentum resolution \(\Delta p/p\) that varies from 0.4% at 5 GeV/c to 0.6% at 100 GeV/c, and an impact parameter resolution of 20 µm for tracks with high transverse momentum \(p_T\). Charged hadrons are identified using two ring-imaging Cherenkov (RICH) detectors. Photon, electron and hadron candidates are identified by a calorimeter system consisting of scintillating-pad and pre-shower detectors, and electromagnetic and hadron calorimeters. Muons are identified by a system composed of alternating layers of iron and multiwire proportional chambers.

The trigger consists of a hardware stage, based on information from the calorimeter and muon systems, followed by a software stage which applies a full event reconstruction. This analysis uses events triggered by one or two muon candidates. In the case of one muon, the hardware level requirement was for its \(p_T\) to be larger than 1.5 GeV/c; in case of two muons the restriction \(\sqrt{p_{T1} \cdot p_{T2}} > 1.3\) GeV/c was applied. At the software level, the two muons were required to have an invariant mass in the interval \(2.97 < m_{\mu^+\mu^-} < 3.21\) GeV/c² and to be consistent with originating from the same vertex. To avoid the possibility that a few events with high occupancy dominate the trigger processing time, a set of global event selection requirements based on hit multiplicities was applied.

For the simulation, pp collisions are generated using PYTHIA 6.4 [9] with a specific LHCb configuration [10]. Decays of hadronic particles are described by EVTGEN [11] in which final state radiation is generated using PHOTOS [12]. The interaction of the generated particles with the detector and its response are implemented using the GEANT4 toolkit [13] as described in Ref. [14]. The digitized output is passed through a full simulation of both the hardware and software trigger and then reconstructed in the same way as the data.

3. Data sample and common selection requirements

The decays \(B^0 \rightarrow J/\psi X^0\) (where \(X^0 = \eta, \eta', \omega\) and \(\pi^+\pi^-\)) are reconstructed using the \(J/\psi \rightarrow \mu^+\mu^-\) decay mode. The \(X^0\) candidates are reconstructed in the \(\eta \rightarrow \gamma\gamma, \eta' \rightarrow \pi^+\pi^-\pi^0, \eta' \rightarrow \rho^0\gamma, \eta' \rightarrow \eta\pi^+\pi^-\) and \(\omega \rightarrow \pi^+\pi^-\pi^0\) final states. Pairs of oppositely charged particles identified as muons, each having \(p_T > 550\) MeV/c and originating from a common vertex, are combined to form \(J/\psi \rightarrow \mu^+\mu^-\) candidates. Well identified muons are selected by requiring that the difference in logarithms of the global likelihood of the muon hypothesis, \(\Delta \ln L_{\muh}\), provided by the particle identification detectors [15], with respect to the hadron hypothesis is greater than zero. The fit of the common two-prong vertex is required to satisfy \(\chi^2/\text{ndf} < 20\), where ndf is the number of degrees of freedom. The vertex is deemed to be well separated from the reconstructed primary vertex of the pp interaction by requiring the decay length significance to be greater than 3. Finally, the invariant mass of the dimuon combination is required to be within \(\pm 40\) MeV/c² of the nominal \(J/\psi\) mass [16].

To identify charged pions the difference between the logarithmic likelihoods of the pion and kaon hypotheses provided by RICH detectors, \(\Delta \ln L_{\pi K}\), should be greater than zero. In the reconstruction of the \(B^0 \rightarrow J/\psi \pi^+\pi^-\) decay this requirement is tightened to be \(\Delta \ln L_{\pi K} > 2\) so as to suppress the contamination from \(B^0 \rightarrow J/\psi \pi K\) decays with misidentified kaons. In addition, the pion tracks are required to have \(p_T > 250\) MeV/c. A minimal value of \(\Delta \chi^2_{\pi}\), defined as the difference between the \(\chi^2\) of the primary vertex, reconstructed with and without the considered track, is required to be larger than four.

Photons are selected from neutral clusters in the electromagnetic calorimeter with minimal transverse energy in excess of 300 MeV. To suppress the large combinatorial background from
π⁰ → γγ decays, photons that can form part of a π⁰ → γγ candidate with invariant mass within ±25 MeV/c² of the nominal π⁰ mass are not used for reconstruction of η → γγ and η′ → ρ⁰γ candidates.

The η → γγ (π⁰ → γγ) candidates are reconstructed as diphoton combinations with invariant mass within ±70(25) MeV/c² around the nominal η(π⁰) mass. To suppress the combinatorial background to the η → γγ decay, the cosine of the decay angle θ*η between the photon momentum in the η rest frame and the direction of the Lorentz boost from the laboratory frame to the η rest frame, is required to have |cos θ*η| < 0.8.

The η' candidates are reconstructed as ηπ⁺π⁻ and ρ⁰γ combinations with invariant mass within ±60 MeV/c² from the nominal η' mass. For the η' → ρ⁰γ case, the invariant mass of the π⁺π⁻ combination is required to be within ±150 MeV/c² of the ρ⁰ mass. For η → π⁺π⁻π⁰ (ω → π⁺π⁻π⁰) candidates the invariant mass is required to be within ±50 MeV/c² of the nominal η(ω) mass.

The B⁰ candidates are formed from J/ψX⁰ pairs with p_T > 3 GeV/c for the X⁰. To improve the invariant mass resolution a kinematic fit [17] is applied. In this fit, constraints are applied on the known masses [16] of intermediate resonances, except the wide ρ⁰ and ω states, and it is also required that the candidate’s momentum vector points to the associated primary vertex. The χ² per degree of freedom for this fit is required to be less than five. Finally, the decay time (cτ) of the B⁰ candidates is required to be in excess of 150 μm.

4. Evidence for the B⁰ → J/ψω decay

The invariant mass distribution of the selected J/ψω candidates is shown in Fig. 2, where a B⁰ signal is visible. To determine the signal yield, an unbinned maximum likelihood fit is performed to this distribution. The signal is modelled by a Gaussian distribution and the background by an exponential function. The peak position is found to be 5284 ± 5 MeV/c², which is consistent with the nominal B⁰ mass [16] and the resolution is in good agreement with the prediction from simulation. The event yield is determined to be Y_B⁰ = 72 ± 15.
The statistical significance for the observed signal is determined as $S = \sqrt{-2 \ln(L_{S+B}/L_B)}$, where $L_{S+B}$ and $L_B$ denote the likelihood of the signal plus background hypothesis and the background hypothesis, respectively. The statistical significance of the signal is found to be 5.0 standard deviations. Taking into account the systematic uncertainty related to the fit function, which is discussed in detail in Section 7.1, the significance is 4.6σ; this also takes into account the freedom in the peak position and width in the nominal fit.

To demonstrate that the signal originates from $B^0 \rightarrow J/\psi \omega$ decays, the sPlot technique [18] has been applied. Using the $J/\psi \pi^+\pi^-\gamma\gamma$ invariant mass as the discriminating variable, the distributions for the invariant masses of the intermediate resonances $\pi^0 \rightarrow \gamma\gamma$ and $\omega \rightarrow \pi^+\pi^-\pi^0$ have been obtained. The invariant mass window for each corresponding resonance is released and the mass constraint is removed.

The invariant mass distributions for $\gamma\gamma$ and $\pi^+\pi^-\pi^0$ from $B^0 \rightarrow J/\psi \omega$ candidates are shown in Fig. 3. Clear signals are seen for both the $\omega \rightarrow \pi^+\pi^-\pi^0$ and $\pi^0 \rightarrow \gamma\gamma$ decays. The $\gamma\gamma$ distribution is described by a sum of a Gaussian function and a constant. The $\omega \rightarrow \pi^+\pi^-\pi^0$ signal is modelled by a convolution of a Gaussian and a Breit–Wigner function with a constant background. The peak positions are in good agreement with the nominal $\pi^0$ and $\omega$ masses and the yields determined from the fits are compatible with the $B^0 \rightarrow J/\psi \omega$ yield. The nonresonant contribution in each case is found to be consistent with zero.

5. Decays into $J/\psi \eta(\prime)$ final states

The invariant mass spectra for $B^0_s \rightarrow J/\psi \eta(\prime)$ candidates are shown in Fig. 4, where signals are visible. To determine the signal yields, unbinned maximum likelihood fits are performed. For all modes apart from $J/\psi \eta(\prime) \rightarrow \rho^0 \gamma$, the $B^0_s$ signal is modelled by a single Gaussian function. In all cases there is a possible corresponding $B^0$ signal, which is included in the fit model as an additional Gaussian component. The difference of the means of the two Gaussians is fixed to the known difference between the $B^0_s$ and the $B^0$ masses [19]. Simulation studies for the $J/\psi \eta(\prime) \rightarrow \rho^0 \gamma$ mode indicate that in this case a double Gaussian resolution model is more appropriate. The mean values of the two Gaussian functions are required to be the same, and the ratio of their resolutions and the fraction of the event yield carried by each of the Gaussian functions are fixed at the values obtained from simulation.

The combinatorial background is modelled by an exponential function. In addition, a component is added to describe the contribution from partially reconstructed $B$ decays. It is described with the phase space function for two particles in a three body decay under the hypothesis of
In Fig. 4, invariant mass distributions for selected $B^0_s \rightarrow J/\psi \eta (\eta \rightarrow \gamma \gamma)$ candidates: (a) $B^0_s \rightarrow J/\psi \eta (\eta \rightarrow \gamma \gamma)$, (b) $B^0_s \rightarrow J/\psi \eta (\eta \rightarrow \pi^+ \pi^- \pi^0)$, (c) $B^0_s \rightarrow J/\psi \eta' (\eta' \rightarrow \rho^0 \gamma)$ and (d) $B^0_s \rightarrow J/\psi \eta' (\eta' \rightarrow \pi^+ \pi^- \eta)$. In all distributions the black dots show the data. The thin solid orange lines show the signal $B^0_s$ contributions and the orange dot-dashed lines correspond to the $B^0_s$ contributions. The blue dashed lines show the combinatorial background contributions and the dotted blue lines show the partially reconstructed background components. The total fit functions are drawn as solid blue lines. The results of the fit are described in the text. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

$B \rightarrow J/\psi \eta^{(*)} X$ decay, where X can be either a kaon or a pion, which escapes detection. The phase space function is convolved with a resolution factor, which is fixed at the value of the signal resolution. The fit results are summarized in Table 1. In all cases the position of the signal peak is consistent with the nominal $B^0_s$ mass [16] and the resolutions agree with the expectations from simulation. The statistical significances of all the $B^0_s$ decays exceed 7$\sigma$.

To test the resonance structure of the $B^0_s \rightarrow J/\psi \eta^{(*)}$ decays, the sPlot technique is used. For the $\pi^0$, $\eta$ and $\eta'$ candidates the background-subtracted invariant mass distributions are studied. The restrictions on the invariant mass for the corresponding resonance are released and the mass...
The background-subtracted invariant mass distributions of the intermediate resonance states from the $B_\mathrm{s}^0 \rightarrow J/\psi X_0$ decays, are shown in Fig. 5. Clear signals are seen. In all cases the signal yields determined from the fits are in agreement with the event yield in the $B_\mathrm{s}^0$ signal within one standard deviation (Table 1). The signal positions are consistent with the nominal masses of the $\eta^{(')}$ mesons and the nonresonant contribution appears to be negligible. In each case the invariant mass resolution agrees with the expectation from simulation studies.

constraints (if any) removed. The background-subtracted distributions are then fitted with the sum of a Gaussian function and a constant component for the resonant and nonresonant components respectively. In the fit of the dipion invariant mass for the $\eta^{(')} \rightarrow \pi^+ \pi^- \gamma$ decay a modified relativistic Breit–Wigner function is used as the signal component [20,21].

6. The $B^0 \to J/\psi \pi^+ \pi^-$ decay

The $B^0 \to J/\psi \rho^0 \left(\rho^0 \to \pi^+ \pi^-\right)$ decay is used as a normalization channel [22]. Since it contains a $J/\psi$ meson and two pions in the final state, the systematic uncertainty is reduced in the ratio of the branching fractions, as the corresponding reconstruction and particle identification uncertainties are expected to cancel.

The invariant mass spectrum for $B^0_{(s)} \to J/\psi \pi^+ \pi^-$ candidates is presented in Fig. 6, where three clear signals are visible. Two narrow signals correspond to the $B^0 \to J/\psi \pi^+ \pi^-$ and $B^0_s \to J/\psi \pi^+ \pi^-$ decays. The latter decay has been studied in detail in Refs. [23,24]. The peak at lower mass corresponds to contamination from $B^0 \to J/\psi K^* \to K^{*0} \pi^- \to K^{*0} \pi^- \to K^{*0} \pi^- \to K^{*0} \pi^- \to K^{*0} \pi^- \to K^{*0} \pi^- \to K^{*0} \pi^- \to K^{*0} \pi^-$ decays with a kaon being misreconstructed as a pion. A contribution from $B^0_s \to J/\psi K^{*0}$ decay is considered to be negligible.

The invariant mass distribution is fitted with a sum of three Gaussian functions to describe the three signals, and an exponential function to represent the background. The fit gives a yield of $1143 \pm 39$ for $B^0 \to J/\psi \pi^+ \pi^-$. Previous studies at BaBar [22] show that the $B^0 \to J/\psi \pi^+ \pi^-$ final state has contributions from decays of $\rho^0$ and $K^0_S$ mesons, as well as a broad S-wave component. A further component from the $f_2(1270)$ resonance is also hinted at in the BaBar study. To study the dipion mass distribution the sPlot technique is used. With the $J/\psi \pi^+ \pi^-$ invariant mass as the discriminating variable, the $\pi^+ \pi^-$ invariant mass spectrum from $B^0 \to J/\psi \pi^+ \pi^-$ decays is obtained (see Fig. 7). A dominant $\rho^0$ signal is observed together with a narrow peak around 498 MeV/c$^2$ due to $K^0_S$ decays. There is also a wide enhancement at a mass close to 1260 MeV/c$^2$. The position and width of this structure are consistent with the interpretation as a contribution from the $f_2(1270)$ state. This will be the subject of a future publication.

The distribution is fitted with the sum of several components. A P-wave modified relativistic Breit–Wigner function [20,21] multiplied by a phase space factor describes the $\rho^0$ signal. A D-wave relativistic Breit–Wigner function is added to describe the enhancement at
Fig. 7. Background-subtracted $\pi^+\pi^-$ invariant mass distribution from $B^0 \to J/\psi \pi^+\pi^-$ decays. The black dots show the data. A violet solid line denotes the total fit function, the solid orange line shows the $\rho^0$ signal contribution and the blue dashed line shows the $f_2(1270)$ contribution. The blue dot-dashed line shows the contribution from the $f_0(500)$. The region ±40 MeV/$c^2$ around the $K_S^0$ mass is excluded from the fit.

1260 MeV/$c^2$. The parameters (width and mean value) of this function are fixed to the known $f_2(1270)$ mass and decay width [16]. The S-wave contribution expected from the $f_0(500)$ resonance is modelled by a Zou and Bugg [25,26] function with parameters from Ref. [27]. The $\rho^0$ parameters (mass and width) are fixed at their nominal values and the region around the $K_S^0$ peak is excluded from the fit. The excluded region is ±40 MeV/$c^2$ which is four times the mass resolution. A small systematic uncertainty is induced by neglecting the $\rho^0$–$\omega$ interference. The value of the uncertainty is estimated to be 0.5% relative to the $\rho^0$ event yield.

The reconstruction and selection efficiency for the dipion system has some dependence on the dipion invariant mass. A study using simulated data has shown that with the increase of the $\pi^+\pi^-$ invariant mass in the range 300–1500 MeV/$c^2$ the efficiency decreases by approximately 16%. As the $\rho^0$ meson has a significant width, this dependence needs to be accounted for in the determination of the $\rho^0$ signal yield. For this, the efficiency dependence on $\pi^+\pi^-$ invariant mass extracted from the simulation is described with a linear function. Then each entry in the invariant mass distribution is given a weight proportional to the inverse value of the efficiency function and the efficiency-corrected invariant mass distribution is refitted with the same sum of functions to extract the efficiency-corrected event yield for $B^0 \to J/\psi \rho^0$. The resulting fit parameters both for the uncorrected and efficiency-corrected distributions are listed in Table 2.
Rapid Communication

**b-quark hadronization fractions** are compared, the ratio of the branching fractions is multiplied by the ratio of the corresponding to the final state under consideration [16]. In cases where decays of different types of B mesons where 

Y fractions of light mesons and B 

develop the total efficiency includes only the detector acceptance and trigger efficiencies, as the reconstruction and selection efficiency for this channel has been discussed in Section 6.

The total efficiencies consist of three components: the geometrical acceptance of the detector, the reconstruction and selection efficiency and the trigger efficiency. For the B0 → J/ψρ0 decay, the event yield Υ implies the value weighted by the selection and reconstruction efficiency from Table 2. Only the acceptance and trigger efficiencies are included in \( \varepsilon_{B0 \rightarrow J/\psi \rho}^{\text{tot}} \). All efficiency components have been determined using the simulation and the values are listed in Table 3.

For channels with photons and neutral pions in the final states, the reconstruction and selection efficiencies are corrected for the difference in the photon reconstruction between the data and simulation. This correction factor has been determined by comparing the relative yields of the reconstructed B+ → J/ψK*+ (K*+ → K+π0) and B+ → J/ψK+ decays. The results of these studies are convolved with the background subtracted photon momentum spectra to give the correction factor for each channel. The values of the correction factors (\( \eta^{\text{corr}} \)) are also listed in Table 3.

### 7.1. Systematic uncertainties

Most systematic uncertainties cancel in the branching fraction ratios, in particular, those related to the muon and J/ψ reconstruction and identification. For the final states with photons the largest systematic uncertainty is related to the efficiency of \( \pi^0/\gamma \) reconstruction and identification, as described above. The uncertainties of the applied corrections reflect simulation statistics, and are taken as systematic uncertainties on the branching fractions ratios.

Another systematic uncertainty is due to the charged particle reconstruction efficiency which has been studied through a comparison between data and simulation. For the ratios where

### 7. Measurements of ratios of branching fractions

Ratios of branching fractions are measured using the formula

\[
R_{B_0 X^0}^{B_{0\psi Y^0}} \equiv \frac{B(B \rightarrow J/\psi X^0)}{B(B \rightarrow J/\psi Y^0)} = \frac{\Upsilon(B \rightarrow J/\psi X^0)}{\Upsilon(B \rightarrow J/\psi Y^0)} \times \frac{B_{Y^0}}{B_{X^0}} \times \frac{\varepsilon_{B_0 \rightarrow J/\psi Y^0}^{\text{tot}}}{\varepsilon_{B_0 \rightarrow J/\psi X^0}^{\text{tot}}},
\]

where \( \Upsilon \) are the measured event yields, \( \varepsilon_{\text{tot}} \) are the total efficiencies, excluding the branching fractions of light mesons and \( B_{X^0}(B_{Y^0}) \) is the relevant branching ratio of the light meson \( X^0(Y^0) \) to the final state under consideration [16]. In cases where decays of different types of B mesons are compared, the ratio of the branching fractions is multiplied by the ratio of the corresponding b-quark hadronization fractions \( f_d/f_s \) [28].

The total efficiencies consist of three components: the geometrical acceptance of the detector, the reconstruction and selection efficiency and the trigger efficiency. For the \( B^0 \rightarrow J/\psi \rho^0 \) decay, the event yield \( \Upsilon \) implies the value weighted by the selection and reconstruction efficiency from Table 2. Only the acceptance and trigger efficiencies are included in \( \varepsilon_{B^0 \rightarrow J/\psi \rho^0}^{\text{tot}} \). All efficiency components have been determined using the simulation and the values are listed in Table 3.

For channels with photons and neutral pions in the final states, the reconstruction and selection efficiencies are corrected for the difference in the photon reconstruction between the data and simulation. This correction factor has been determined by comparing the relative yields of the reconstructed B+ → J/ψK*+ (K*+ → K+π0) and B+ → J/ψK+ decays. The results of these studies are convolved with the background subtracted photon momentum spectra to give the correction factor for each channel. The values of the correction factors (\( \eta^{\text{corr}} \)) are also listed in Table 3.
Table 4
Relative systematic uncertainties for ratios of the branching fractions ($\mathcal{R}$) for the $B^0 \to J/\psi \eta^{(')}$ channels [%].

this does not cancel exactly, the corresponding systematic uncertainty is taken to be 1.8% per pion [29].

The systematic uncertainty related to the trigger efficiency has been obtained by comparison of the trigger efficiency ratios in data and simulation for the high yield decay mode $B^\pm \to J/\psi K^\pm$ with similar kinematics and the same trigger requirements [30]. This uncertainty is taken to be 1.1%.

In the ratios where decays of B mesons of different types are compared ($B^0$ or $B^0_s$), knowledge of the hadronization fraction ratio $f_d/f_s$ is required. The measured value of this ratio [28] has an asymmetric uncertainty of $+7.9\% - 7.5\%$.

Systematic uncertainties related to the fit model are estimated using a number of alternative models for the description of the invariant mass distributions. For the $B^0_s \to J/\psi \eta^{(')}$ decays the tested alternatives include a fit without the $B^0$ component, a fit with the means of the Gaussians fixed to the nominal B meson masses, a fit with the width of the Gaussians fixed to the expected mass resolutions from simulation and substitution of the exponential background hypothesis with first- and second-order polynomials. This uncertainty is calculated for the ratios of the event yields. For each alternative fit model the ratio of the event yields is calculated and the systematic uncertainty is then determined as the maximum deviation of this ratio from the ratio obtained with the baseline model.

A similar study is performed for the $B^0 \to J/\psi \omega$ channel. As the fit with one Gaussian function is the baseline model in this case, here the alternative model is a fit with two Gaussian functions (allowing a possible $B^0_s$ signal).

In the $B^0 \to J/\psi \rho^0$ case, an alternative model replaces the Zou–Bugg $f_0(500)$ term with a Breit–Wigner shape. The mass and width of the broad $f_0(500)$ state are not well known. The mass measured by various experiments varies in a range between 400 and 1200 MeV/$c^2$ and the measured width ranges between 600 and 1000 MeV/$c^2$ [16]. Therefore, the $f_0(500)$ parameters are varied in this range and the $\rho^0$ yield is determined. Again, the maximum deviation from the baseline model is treated as the systematic uncertainty of the fit.

The uncertainties related to the knowledge of the branching fractions of $\eta$, $\eta'$, $\pi^0$ and $\omega$ decays are taken from Ref. [16]. Other systematic uncertainties, such as those related to the selection criteria are negligible. The systematic uncertainties are summarized in Tables 4 and 5. The total systematic uncertainties are estimated using a simulation technique (see Section 7.2).

7.2. Results

The final ratios $\mathcal{R}_{B^0, \eta}$, $\mathcal{R}_{B^0, \eta'}$, $\mathcal{R}_{B^0, \rho^0}$ and $\mathcal{R}_{B^0, \omega}$ are determined using a procedure that combines $\chi^2$-minimization with constraints and simplified simulation. First, the $\chi^2$ is minimized

$$
\chi^2 = \sum_i \chi_i^2 
$$

where the sum is performed over the six measured event yields for the six different modes: $B^0 \rightarrow J/\psi \eta (\eta \rightarrow \gamma \gamma)$, $B^0_s \rightarrow J/\psi \eta (\eta \rightarrow \pi^+ \pi^- \pi^0)$, $B^0 \rightarrow J/\psi \eta' (\eta' \rightarrow \rho^0 \gamma)$, $B^0_s \rightarrow J/\psi \eta' (\eta' \rightarrow \pi^+ \pi^-)$, $B^0 \rightarrow J/\psi \omega$ and $B^0 \rightarrow J/\psi \rho^0$, and $\chi_i^2 = \frac{(x_i - \bar{x}_i)^2}{\sigma_i^2}$. In this procedure the following constraints are imposed

$$
\frac{\mathcal{Y}_{B^0_s \rightarrow J/\psi \eta (\eta \rightarrow \gamma \gamma)}}{\varepsilon_{B^0_s \rightarrow J/\psi \eta (\eta \rightarrow \gamma \gamma)} \times B(\eta \rightarrow \gamma \gamma)} = \frac{\mathcal{Y}_{B^0 \rightarrow J/\psi \eta (\eta \rightarrow \pi^+ \pi^- \pi^0)}}{\varepsilon_{B^0 \rightarrow J/\psi \eta (\eta \rightarrow \pi^+ \pi^- \pi^0)} \times B(\pi \rightarrow \pi^+ \pi^- \pi^0)},
$$

$$
\frac{\mathcal{Y}_{B^0_s \rightarrow J/\psi \eta' (\eta' \rightarrow \rho^0 \gamma)} \times B(\eta' \rightarrow \rho^0 \gamma)}{\varepsilon_{B^0_s \rightarrow J/\psi \eta' (\eta' \rightarrow \rho^0 \gamma)} \times B(\eta' \rightarrow \rho^0 \gamma)} = \frac{\mathcal{Y}_{B^0 \rightarrow J/\psi \eta' (\eta' \rightarrow \pi^+ \pi^-)} \times B(\eta' \rightarrow \pi^+ \pi^-)}{\varepsilon_{B^0 \rightarrow J/\psi \eta' (\eta' \rightarrow \pi^+ \pi^-)} \times B(\eta' \rightarrow \pi^+ \pi^-)}.
$$

The ratios $R_{B^0_s, \eta', \eta}$, $R_{B^0_s, \eta}$, and $R_{B^0, \rho^0}$ are determined using the event yields obtained from the minimization procedure. For this determination the efficiencies $\varepsilon_i$ have been varied using a simplified simulation taking into account correlations between the various components where appropriate. As both the $\chi^2$ and the ratios $R$ depend only on the ratios of efficiencies, systematic uncertainties are minimized. The remaining systematic uncertainties have been taken into account as uncertainties in the efficiency ratios. In total, $10^6$ simulated experiments with different settings of $\varepsilon_i$ have been performed. The symmetric 68% intervals have been assigned as the systematic uncertainty.

The obtained ratios $R$ are

$$
R_{B^0_s, \eta', \eta} = 0.90 \pm 0.09^{+0.06}_{-0.02},
$$

$$
R_{B^0_s, \eta} = (3.75 \pm 0.31^{+0.30}_{-0.40}) \times \left( \frac{f_d}{f_s} \right),
$$

$$
R_{B^0_s, \rho^0} = (3.38 \pm 0.30^{+0.14}_{-0.36}) \times \left( \frac{f_d}{f_s} \right),
$$

$$
R_{B^0, \rho^0} = 0.89 \pm 0.19^{+0.07}_{-0.13},
$$

where the first uncertainty is statistical and the second is systematic.
8. Summary

With 1.0 fb$^{-1}$ of data, collected in 2011 with the LHCb detector, the first evidence for the \( B^0 \to J/\psi \omega \) decay has been found, and its branching fraction, normalized to that of the \( B^0 \to J/\psi \rho^0 \) decay, is measured to be

\[
\frac{B(B^0 \to J/\psi \omega)}{B(B^0 \to J/\psi \rho^0)} = 0.89 \pm 0.19 \text{(stat)}^{+0.07}_{-0.13} \text{(syst)}. 
\]

Multiplying by the known value of \( B(B^0 \to J/\psi \rho^0) = (2.7 \pm 0.4) \times 10^{-5} \) [22], the absolute value of the branching fraction is

\[
B(B^0 \to J/\psi \omega) = (2.41 \pm 0.52 \text{(stat)}^{+0.19}_{-0.35} \text{(syst)} \pm 0.36 \text{(syst)}) \times 10^{-5}. 
\]

Using the same dataset, the ratio of the branching fractions of \( B^0_s \to J/\psi \eta \) and \( B^0_s \to J/\psi \eta' \) decays has been measured. As each of the decays has been reconstructed in two final states, the resulting ratio has been calculated through an averaging procedure to be

\[
\mathcal{R}_{B^0_s, \eta'}^{B^0_s, \eta} = \frac{B(B^0_s \to J/\psi \eta')}{B(B^0_s \to J/\psi \eta)} = 0.90 \pm 0.09 \text{(stat)}^{+0.06}_{-0.02} \text{(syst)}. 
\]

This result is consistent with the previous Belle measurement of \( \mathcal{R}_{B^0_s, \eta'}^{B^0_s, \eta} = 0.73 \pm 0.14 \) [3], but is more precise. Assuming that the contribution from the purely gluonic component is negligible, this ratio corresponds to a value of the \( \eta-\eta' \) mixing phase of \( \phi_F = (45.5^{+1.8}_{-1.5})^\circ \). The branching fractions of the \( B^0_s \to J/\psi \eta \) and \( B^0_s \to J/\psi \eta' \) decays have been determined by normalization to the \( B^0 \to J/\psi \rho^0 \) decay branching fraction, and using the known value of \( f_s/f_d = 0.267^{+0.021}_{-0.020} \) [28] their ratios are

\[
\frac{B(B^0_s \to J/\psi \eta)}{B(B^0 \to J/\psi \rho^0)} = 14.0 \pm 1.2 \text{(stat)}^{+1.1}_{-1.5} \text{(syst)}^{+1.1}_{-1.0} \left( \frac{f_d}{f_s} \right),
\]

\[
\frac{B(B^0_s \to J/\psi \eta')}{B(B^0 \to J/\psi \rho^0)} = 12.7 \pm 1.1 \text{(stat)}^{+0.5}_{-1.3} \text{(syst)}^{+1.0}_{-0.9} \left( \frac{f_d}{f_s} \right). 
\]

When multiplying by the known value of \( B(B^0 \to J/\psi \rho^0) \), the branching fractions are measured as

\[
B(B^0_s \to J/\psi \eta) = \left( 3.79 \pm 0.31 \text{(stat)}^{+0.20}_{-0.41} \text{(syst)}^{+0.29}_{-0.27} \left( \frac{f_d}{f_s} \right) \pm 0.56 \text{(syst)} \right) \times 10^{-4}, 
\]

\[
B(B^0_s \to J/\psi \eta') = \left( 3.42 \pm 0.30 \text{(stat)}^{+0.14}_{-0.35} \text{(syst)}^{+0.26}_{-0.25} \left( \frac{f_d}{f_s} \right) \pm 0.51 \text{(syst)} \right) \times 10^{-4}. 
\]

The branching fractions measured here correspond to the time integrated quantities, while theory predictions usually refer to the branching fractions at \( t = 0 \). Special care needs to be taken when the \( B^0_s \) and \( B^0 \) decays are compared at the amplitude level, corresponding to the branching ratio at \( t = 0 \) [31]. Since the \( J/\psi \eta^{(*)} \) final states are \( CP \)-eigenstates, the size of this effect can be as large as 10%, and can be corrected for using input from theory or determined from effective lifetime measurements [31]. With a larger dataset such measurements, as well as studies of \( \eta-\eta' \) mixing and measurements of \( CP \) asymmetries in the \( B^0_s \to J/\psi \eta^{(*)} \) modes will be possible.
Acknowledgements

We would like to thank A.K. Likhoded for many fruitful discussions. We express our gratitude to our colleagues in the CERN accelerator departments for the excellent performance of the LHC. We thank the technical and administrative staff at CERN and at the LHCb institutes, and acknowledge support from the National Agencies: CAPES, CNPq, FAPERJ and FINEP (Brazil); CERN; NSFC (China); CNRS/IN2P3 (France); BMBF, DFG, HGF and MPG (Germany); SFI (Ireland); INFN (Italy); FOM and NWO (The Netherlands); SCSR (Poland); ANCS (Romania); MinES of Russia and Rosatom (Russia); MICINN, XuntaGa and GENCAT (Spain); SNSF and SER (Switzerland); NAS Ukraine (Ukraine); STFC (United Kingdom); NSF (USA).
